June 29.....	1117 to	1160

A

Abaca industry of Philippine Islands, Cox.	*285
Accelerators. Vulcanization: (see under Rubber)	
Acetaldehyde from acetylene. Plauson and Vielle. (B. P.)	*938
Acetic acid:	
—Catalysts for mfr. of. Plauson and Vielle. (B. P.)	896
—From acetaldehyde. (B. P.)	708
—From acetaldehyde. Dreyfus. (B. P.)	708
—From acetylene. Plauson and Vielle. (B. P.)	*938
—From suction gas plants using wood. Roberts. (B. P.)	*272
Acetone:	
—Purification of. Duclaux and Lanzenberg. (S.)	34
—From starch. Nasmyth. (N.)	534
Acetyl chloride, mfr. of. Kaufmann (P.)	36
Acid-resisting materials:	
—Alloy for chemical apparatus. Fahrwald. (P.)	36
—Iron:Chromium alloy articles. Clement. (P.)	1028
Aeronautics. Contribution of chemistry to. Moureu. (S.)	34
Agassiz Medal to be presented to Prince of Monaco	668
Air Reduction Co. acquires National Carbide Corp.	801
Alaska:	
—Wood pulp mill at Juneau	535
Alberta:	
—Oil and gas claims in.	534
Alcobronze (N.)	220
ALCOHOL:	
—Alcohol and chemical industries. Doran. (N.)	829
—Changes considered in methods of distribution	185
—Changes in Regulation 60.	176
—From nipa palm. Gibbs. (N.)	404
—From wood waste. Yields of.	212
—Preventing use as intoxicant. Kramer.	373
—Volstead supplementary prohibition bill:	
—Objectionable sections	1076
—Protest meeting. N. Y. section. A. C. S.	1088
—Committee on Rules reverses attitude on	1159
Alizarine from benzene. Schaffer. (N.)	831
Alkaloids:	
—Separation of. (B. P.)	402
Allied Chemical & Dye Corp. directors...	7
Alloys:	
—Effect of metallic structure upon properties. Rawdon.	*523
—Properties of. Tabulated. Woodward.	820
—Ternary. Coefficients of equivalence in. Guillet and Portevin. (S.)	*609
Alsace:	
—Alsatian potash industry. Vigneron.	*655
—Potash production, 1920.	921
Alsberg, Dr. Carl L., becomes director of Stanford University Food Research Institute	*648
Alum, Potash, Recovery at Tonopah. Duncan.	*529
Alumina from basic aluminum nitrate. (B. P.)	38
ALUMINUM:	
—Causes of piping in ingots. Edwards and Gammon	*338
—Density from 20 to 1,000 deg. C. Edwards and Moormann.	*61
—Gases in aluminum furnaces and their analysis. Anderson and Capps.	*1019
—Recrystallization in. Carpenter and Elam. (S.)	1117

ALUMINUM—Continued:

—Use for electric transmission lines. Dusaugy. (S.)	313
—Coating metals with. (B. P.)	984
—Production, 1920	536
Aluminum nitride research. McCormack. (N.)	757
Aluminum sulphate used in water-purification, Illinois, 1920.	856
American Association for the Advancement of Science:	
—Chicago meeting, Report.	83
AMERICAN CERAMIC SOCIETY:	
—Columbus meeting:	
—Announcement	316
—Report.	419
—Canton meeting:	
—Announcement	1073
AMERICAN CHEMICAL SOCIETY:	
—Rochester meeting:	
—Symposiums on drying and filtration planned	87, 358
—Preliminary program	533
—Addition to program	577
—Program	710
—Report	*821
—New York meeting:	
—Hotel accommodations	1030
—Gas and fuel symposium planned.	1118
AMERICAN ELECTROCHEMICAL SOCIETY:	
—Atlantic City meeting:	
—Preliminary announcement	316
—Program	623
—Report	*813
—Lake Placid meeting plans	988
AMERICAN ENGINEERING COUNCIL:	
—Progress of.	39
—Assumes activities of Engineering Council	86
—Opens office in Washington	229
—To meet in Syracuse	229
—Wallace elected secretary	*357
—Begins war on industrial waste	358
—Hoover resigns as president	709
—Executive board meets	709
American Engineering Standards Committee:	
—Activities of	665
AMERICAN INSTITUTE OF CHEMICAL ENGINEERS:	
—Detroit meeting:	
—Program	939
AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS:	
—New York meeting:	
—Announcement	227
—Report	329
AMERICAN LEATHER CHEMISTS' ASSOCIATION:	
—Atlantic City meeting:	
—Preliminary program	854
—Final program	1030
—Report	*1094
American Leather Research Laboratories.	27
American Mining Congress:	
—Chicago convention plans	490
AMERICAN OIL CHEMISTS' SOCIETY:	
—Aims and organization	535
—Chicago meeting:	
—Plans	713
—Report	957
AMERICAN SOCIETY OF MECHANICAL ENGINEERS:	
—Chicago meeting:	
—Steam equipment codes to be discussed	624
—Plans	753
—Inspection trips planned	800
—Report	1031
American Society of Refrigerating Engineers:	
—Chicago meeting	1074
AMERICAN SOCIETY FOR STEEL TREATING:	
—Indianapolis meeting:	
—Announcement	449
—Program	1033
AMERICAN SOCIETY FOR TESTING MATERIALS:	
—Asbury Park meeting:	
—Report	1145
Amines, Aromatic, Mfr. of. Moore. (B. P.)	796
AMMONIA:	
—Oxidation at Oppau, Germany	*348
—Distilling column for. Crupe. (P.)	*851
—Synthetic:	
—Mfr. at Oppau, Germany	I. *305
	II. *347
	III. *391
—Status of Claude process. Claude. (S.)	706
—Catalyst for. (B. P.)	402, 489, 1116
Ammonia-soda process. Nishigawa (P.)	133
—Modified. Claude. (B. P.)	1156
Ammonium chloride:	
—As fertilizer	16
—Mfr. at Oppau, Germany	*391

Ammonium nitrate:

—Mfr. at Oppau, Germany	*392
Ammonium phosphate as fertilizer.	12
AMMONIUM SULPHATE:	
—Mfr. at Oppau, Germany	*391
—Saturators for. Becker. (P.)	664
—Drying. Wilton. (B. P.)	*621
—Purification of. Lessing. (B. P.)	*315
—Semi-direct method. (B. P.)	*402
Anaconda Copper Mining Co. extensions.	898
Annual Tables of Constants and Numerical Data	853, 986
Anthranol, Mfr. of. Perkin. (B. P.)	226
Anthraquinone, mfr. of. (B. P.)	937
—Temperature control in catalytic mfr. of. Downs. (P.)	*1027
Anthraquinone derivative, Synthetic. Weiss, Bailey and Potter. (P.)	35
Anthraquinone derivatives and dyes. Casella. (B. P.)	489
Antimony ores. Tariff problems	1003
Apparatus, Duty-free, For colleges, Richards	52
—Comment. Smith.	284
Argentina:	
—Vegetable oil industry in	612
Armour Fertilizer Works. Jones.	I. *333
	II. *379
—Correction. Jones	548
Arsenic:	
—Removal from zinc electrolyte by H.S. Hanley	*693
—Automatic detector for arsenic gases. Logan. (B. P.)	38
—Single potential of. Kahlenberg. (N.)	83
Arsenic compounds, Organic:	
—Arsenobenzene derivatives. Haus. (B. P.)	852
Arsenic trioxide:	
—Mfr. of. Vie.	*527
—Tariff hearings on.	403
—Plant at Toulon, Nev.	536
Artillery cartridge cases. Read and Tour. (N.)	330
Atlas Powder Co. to produce refining carbon	1119
Atoms and metals. Jeffries and Archer.	*507
B	
Bacteria as chemical reagents. Kendall.	56
Bain, H. Foster, becomes director, Bureau of Mines	*179
Bamboo paper pulp plant in Burma.	250
Barrels for petroleum products, mfr. of. Baxter. (N.)	360
Barrett Co.:	
—Board of directors	*7
—Shadyside research laboratories. Weiss and Downs.	*150
Basic Refractories, Inc., Plant destroyed by fire	273
Batteries, Secondary:	
—Drying plates for.	*267
—High-capacity storage battery. Hazlett. (N.)	819
Bauxite, Trade notes on. Coggin. (S.)	707
—Tariff problems	1004, 1006
BELGIUM:	
—Coal production	608
—Experiments on palm oil as motor fuel.	400
—Foreign commerce in 1920.	845
—Metallurgical industries in 1920.	604
—Progress of chemical industry.	1070
—Status of iron and steel industry.	387
Belting:	
—Use in fertilizer plants. (S.)	706
Benzanthrone, Purification of. Daniels. (P.)	488
BENZENE:	
—New type of benzene still in European operation. Thau.	*1013
—Recovery from acid sludge. Crook. (B. P.)	*226
—Removing sulphur compounds. (B. P.)	272
Benzoic acid, Chlorine-free, Synthesis from benzene. McKee and Strauss. I.	*638
	II. *697
Bichromates, mfr. of. Datta. (B. P.)	796
BIOGRAPHICAL:	
—Alsberg, Carl L.	*648
—Bain, H. Foster.	*179
—Ciamician, Giacomo	549
—Curie, Mme. M. S.	1132, 1137
—Feiker, Frederick M.	*913
—Hadfield, Sir Robert	*1147
—Le Chatelier, Henry Louis	549
—Lewis, Gilbert N.	*869
—Lloyd, John Uri	550
—Nichols, Ernest Fox	*682
—Nichols, William Henry	550
—Smith, Edgar Fahs	*183, 550
—Solvay, Ernest	549
—Thompson, Benjamin. (Count Rumford)	252
—Thorpe, Sir Edward	549
—Wallace, Lawrence W.	*357
—Weston, Edward	550
—Whitney, Willis R.	*99

*Illustrated; (P.), (B. P.)—United States and British patents respectively; (S.)—Synopsis; (N.)—Papers read at society meetings but not printed in full.

- Bismuth concentrates, Chinese, Refining. Darling. 1108
- Bleaching cotton goods, Chlorine control in. Schroeder. *925
- Bleaching dyed cotton fabrics. Matthews. (N.) 832
- Bluing and browning steel articles. Cornell. 301
- Book Reviews. 41, 137, 230, 318, 362, 405, 449, 492, 536, 580, 668, 714, 982, 1029, 1120.
- BOOK REVIEWS:
- Allen. Recovery of Nitrate from Chilean Caliche. 1161
- Andros. Fuel Oil in Industry. 449
- Camp and Francis. The Making, Shaping, and Treating of Steel. 137
- Clark. The Determination of Hydrogen Ions. 714
- Cushman. Chemistry and Civilization. 230
- Foote, Fairchild and Harrison. Pyrometric Practice. 1029
- Goodale and Speer. Chronology of Iron and Steel. 580
- Harrow. Eminent Chemists of Our Time. 318
- Heriot. The Manufacture of Sugar from the Cane and Beet. 405
- Hoyt. Metallography, Part II. 1160
- Hultgren. A Metallographic Study on Tungsten Steels. 1120
- Johnson. Rapid Method for the Chemical Analysis of Special Steels, Steel-making Alloys, Their Ores and Graphites. 668
- Macleod. Textbook of Chemistry for Nurses and Students of Home Economics. 362
- Matthews. Application of Dyestuffs. 318
- McCoy and Terry. Introduction to General Chemistry. 983
- Osann. Lehrbuch der Eisen und Stahlgiesserei. 536
- Patterson. A French-English Dictionary for Chemists. 1121
- Ralston. Electrolytic Deposition and Hydrometallurgy of Zinc. 492
- Scott. The Journal of the Institute of Metals. 449
- Smith. Priestley in America. 137
- Speer and Goodale. Chronology of Iron and Steel. 580
- Sutermeister. Chemistry of Pulp and Paper Making. 580
- Van der Bijl. The Thermionic Vacuum Tube and Its Applications. 669
- Whitby. Plantation Rubber and the Testing of Rubber. 41
- Comment. Whitby. 417
- White. Silver. Its Intimate Association With the Daily Life of Man. 982
- Windett. The Open Hearth—Its Relation to the Steel Industry—Its Design and Operation. 982
- MacRae's Blue Book. 406
- The Microscope. 1161
- Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists. 982
- Proceedings of the Chicago Meeting of the Industrial Relations Association of America. 492
- Research and Methods of Analysis of Iron and Steel. 1029
- Borax mfr. at Owens and Searles Lakes. *685
- Boric acid from boro-natro-calcite. Schott & Ges. (B. P.) 489
- BRASS:
- Season cracking of. Beckinsale and Mallinson. *976
- Ternary brasses. Guillet. (S.) *177
- Nickel brasses. Guillet. (S.) *261
- Cobalt brasses. Guillet. (S.) *439
- Coefficients of equivalence in ternary alloys. Guillet and Portevin. (S.) *609
- Influence of gases on high-grade. Bamford and Ballard. (S.) 132
- Scrap. Treating. Ralston. (P.) 1115
- Bregeat process for solvent recovery. Rolleux and Dort. *916
- Brinell hardness tester, Modified. (B. P.) *226
- British-American Nickel Corporation, Development of. 228
- British Chemical Industry. 85, 196, 418, 594, 812, 1001.
- BRITISH COLUMBIA:
- Paper possibilities. 183
- Prince Rupert Pulp & Paper Co. sulphite mill. 492
- Imperial Oil Co. refinery to resume. 492
- Industrial notes. 536
- Sodium Mining & Products Co. plant. 1158
- Bromine in 1920. 1108
- Browning and bluing steel articles. Cornell. 301
- Buenos Aires exposition delayed. 533
- Buffalo University chemistry building. 899
- BUREAU OF MINES:
- Cryogenic laboratory dedication. *914
- H. Foster Bain becomes director of. *179
- Appropriations reduced. 40
- Appropriation asked for study of non-metallic structural materials. 797
- Discussion of western metallurgical problems. 185
- May study Black Hill ores. 580
- Officials to visit mining experiment stations. 577
- Technical motion pictures. 1031
- BUREAU OF STANDARDS:
- Recent work of. Wagner. (N.) 799
- Standard steel and bronze samples. 160
- Standard iron and steel samples. 492
- Burgess nominated for Tariff Commission. 1157
- Burns, Acid and alkali, Treatment of. Smith. 748
- Comment. Goetschius. 868
- Butyl alcohol and acetone from starch. Nasmith. (N.) 534
- C
- Cadmium lithopone. Webster. 372
- Calcium carbide, mfr. in blast furnace. Norton. (P.) 1027
- Calcium requirement of man (S.) 129
- Calcium silicide as deoxidizer. 980
- Calomel electrode. Laubengayer. (N.) 819
- Camphor:
- New tariff proposed. 360
- Production in the United States. 185
- Taiwan production. 926
- Camsellite, A new mineral. 1158
- CANADA:
- Coal trade for 1920. 599
- Foreign trade, 1920. 584
- Gas industry in 1918. 785
- Oil field developments in. 856
- Pulpwood resources of. 208
- Cans for petroleum products, mfr. of. Baxter. (N.) 360
- Canvas. Treated. Water resistance of. Veitch. (N.) 831
- Capillary flow and surface tension. Washburn (S.) 314
- Capital Increases, etc. 412, 456, 499, 544, 588, 631, 720, 764, 864, 907, 951, 995, 1040, 1084, 1128, 1168.
- Carbon bisulphide:
- Mfr. in blast furnace. McElroy. (P.) 707
- Carbon monoxide detection. Hoover. (N.) 830
- Caribbean ports, Trade trip to. 275
- Cartridge cases, Artillery. Read and Tour. (N.) 330
- Casein specifications and tests. (N.) 727
- Casein compounds. Hoffmann-La Roche. (B. P.) 708
- Casein glue affected by chemical reaction. 964
- Castor oil:
- Castor bean production in Java. 384
- Catalysis:
- Catalyst for synthetic ammonia. (B. P.) 402
- Temperature control during. Downs. (P.) *1027
- Cellulose:
- Action of hydrobromic acid on. Hibbert. (N.) 834
- Standard cellulose proposed. Johnsen. (N.) 834
- Tropics as future source of. Whitford. (N.) 833
- Cellulose acetate:
- European practice. Drinker. (N.) 834
- Dyeing. (B. P.) 1116
- Solvents for use with. Dreyfus. (B. P.) 708
- Cellulose Section, A. C. S.: 833
- Rochester meeting report. 833
- Cement:
- German industry. 688
- State-owned plant in South Dakota. 667
- Cements:
- Hydrocarbon. Barrie and Chadwick. (B. P.) 621
- Central Leather Co. report. 448
- CERAMICS:
- Bureau of Mines may study non-metallic structural materials. 797
- Ceramic appropriation fails in Ohio. 578
- Ceramic exposition in Newark, N. J. 801
- Co-operative work in. 668
- Co-operative work planned. 492
- Electric heating in. Scott. 400
- Problems to be solved. Minton. (N.) 419
- Research in ceramic decorative processes. Rhead. (S.) 1117
- Research on Colorado ceramic resources. 579
- Chandler Medal awarded to Dr. F. G. Hopkins. 668
- Charcoal absorption process for gasoline. Burrell, Oberfell and Voress. *156
- Charts:
- Calculation of percentage removal of a constituent from a mixture. Van Arsdell. *846
- Chemical and Allied Industrial Markets. 42, 90, 139, 187, 230, 275, 319, 362, 406, 450, 493, 537, 582, 625, 670, 714, 758, 801, 857, 901, 945, 989, 1034, 1078, 1121, 1162.
- Chemical companies formed. New. 943
- Chemical disarmament. Lefebure. 5
- Chemical engineering education survey. 1047
- Chemical imports and exports:
- January, 1921. 535
- February. 757
- Chemical literature. Investigations of. Barrows. I. 423
II. 477
III. 517
- Correction. Van Patten. 548
- Chemical organization and management. Whittaker. (N.) 136
- Chemical preparedness. Wadsworth. (N.) 822
- Chemical Products Co. closes plant. 491
- Chemical reactions. Effecting under pressure. Schellenberg. (B. P.) *984
- Chemical tonnage on Class 1 railroads. 779
- CHEMICAL WARFARE SERVICE:
- Fries advocates plan to stimulate inventive initiative. 89
- Service school opens. 136
- A. C. S. advisory committee to meet. 228
- Resolution to be submitted to A. C. S. 273
- CHEMICAL WARFARE SERVICE—Continued:
- Appropriation. 273
- Investigating alleged gas injuries. 361
- Needs commissioned personnel. 447
- Report by War Dept. committee on expenditures. 491
- Chemical warfare exhibit. *512
- At Wilmington. 942
- At House Office Building. 943
- Dinner:
- Announcement. 665
- Report. *754
- Legislators visit Edgewood Arsenal. 624
- Senator Lenroot's opinion of visit. 668
- A. C. S. committee to visit Edgewood. 713
- To concentrate work at Edgewood. 709
- To test gas bombs in aerial warfare. 899
- General staff college hears of. 897
- Appropriation. 941
- Anniversary exercises at Edgewood Arsenal. 1073
- Chemical Warfare Service Association proposed. 580
- Chemicals moved through Panama Canal in March. 985
- Chemists:
- Who is a chemist? McCormick. Perino. 416
- Comment. Kaempfert. 593
- Comment. Kaempfert. 956
- Compensation of chemists and salesmen. Ferguson. 460
- Comment. Chemist. 637
- Business and chemists. Giston. 461
- Chemists Club:
- Tenth annual meeting:
- Announcement. 448
- Report. *549
- Chemistry. Language of. B. T. B. 548
- Chewing gum. Gutta-gaekwar as base for. Dannerth. 308
- Chia seed oil. Industrial possibilities of. 82
- Chicago Chemists Club:
- Smoker. 361
- Annual meeting. 667
- Ladies' night. 756
- Hike over dunes. 987
- Chicago Section, A. C. S.: 1075
- February meeting. Uses of lead. 317
- May meeting. 1075
- Chicago Section, A. C. S.: 229
- January meeting. Home remedies. 448
- February meeting. Redmanol. 800
- April meeting. Photochemistry. 986
- May meeting. Oxidation. 986
- Chicago University reports favorably on research plan. 942
- Chilean nitrate:
- Exports for 1920. 557
- Recovery of. Gringioni. (B. P.) *532
- Chimneys:
- Steel. In copper plants. McGregor. (N.) 329
- China:
- Economic and political conditions. Chan. (N.) 136
- Egg products industry. 16
- Sugar project in. 845
- Chinawood oil. Solidified. Scobel. 532
- Chloridizing complex ores. Hamilton. (B. P.) 271
- CHLORINE:
- Control in bleaching cotton goods. Schroeder. *925
- Attempt to activate photometrically. Wendt. (N.) 8?
- Electrolytic chlorine caustic cells:
- Rise and development of the electrolytic alkali and chlorine industry in Europe. Kershaw. I. *77
II. *119
III. *167
- Comment. Hutchins. 506
- Marsh type. Marsh. (N.) 819
- Chloroform from isopropyl alcohol. Phillips. (P.) 36
- Chromite. Tariff problems. 1004
- Civil Service Examinations 447, 491, 622, 666, 899.
- Classifiers. Upward current ore. Jalabert. (B. P.) *938
- Clay. Aging of. Spurrier. (S.) 620
- Clay storage within factory. (S.) 260
- Cleaning metallic materials. 209
- Cloths for mechanical uses. Cox. 613
- Coal:
- Extraction of hydrocarbons from. Plauson and Vielle. (B. P.) 937
- Pulverized coal. 251
- Gasification of. Bourcoud. *601
- Coal-tar:
- Research at Shadyside. Weiss and Downs. *150
- Chemicals in 1919. Tariff census. (S.) 180
- Cobalt:
- And nickel separating. Udy and Ralston. (P.) 489
- Cobalt brasses. Guillet. (S.) *439
- Cobalt oxide. Tariff problems. 1003
- Coconut oil:
- Mill situation in Dutch East Indies. 378
- Problems in preparation of copra and. Brill. 567
- Coke:
- Byproduct coke plant of Jones & Laughlin Steel Co. Meissner. *891
- Byproduct coke plants in United States. 1056
- Coke ovens:
- Charging car for. Becker. (P.) *1115
- Wallace retort. Wallace. (P.) 36
- Construction of. Koppers. (P.) 664
- Colloidal clay as paper filler. 580
- COLLOIDS:
- Survey of physics and chemistry of. Svedberg. 23
- *Illustrated; (P.) (B. P.)—United States and British patents respectively; (S.)—Synopsis; (N.)—Papers read at society meetings but not printed in full.

COLLOIDS—Continued:

- A. C. S. symposium on contact catalysis (N.) 837
- Border lines of colloid chemistry. Comment. Loeb. 681
- Industrial applications of. Holmes. (N.) 579
- Colloids. Holmes. (N.) 1096
- Preparation of colloidal suspensions by grinding. Plauson and Vielle. (B. P.) 852
- Color:**
- Colloid chemistry and. Bancroft. (N.) 824
- Measurement of. Mees. (N.) 824
- Chemical constitution and. Lewis. *871
- Columbia University:**
- New chemistry building for 797
- Condenser, multiwhirl subcooling *267
- Connecticut Valley Branch, T. A. P. P. I.:**
- January meeting. Rubber rolls. 228
- February meeting. Drying of paper. 361
- April meeting. Dyes 800
- May meeting. Water purification. 1077
- Constants, Chemical and physical:**
- Annual Tables of 853, 986
- Critical tables of 1158

INDEX

SULPHUR:

- Recent advances in American sulphur industry. Bacon and Davis. *65
- Recovery by flotation at Tonopah. Duncan. *529
- Growth of American industry 1021
- Inoculated sulphur as fertilizer 10
- Moving pictures of Texas deposit shown at T. A. P. P. I. 727
- Refinery at Portland, Ore. 22
- Sulphur burners. Feeding device for. Chappell. (P.) *752
- Sulphur dioxide:
 - May have therapeutic value. Ionides. 284

SULPHURIC ACID:

- Mills-Packard water-cooled chambers. Fairlie. *786
- Mfr. at Armour Fertilizer Works. *333
- Ceco system for handling *380
- Influence of gelatine on transference number of. Ferguson. (N.) 838
- Municipal plant proposed in England 780
- Cleaning burner gases for. Brown. (P.) 576
- Vanadium catalyst for contact process. Slama and Wolt. (P.) 752
- Sulphuric chloride. Mfr. of. Durrans. (P.) 488
- Sumac production in Sicily 604
- Superpower Survey:
 - Progress report on 445
 - Meeting 941
- Surface films as plastic solids. Wilson. (N.) 825
- Surface tension and capillary flow. Washburn. (S.) 314
- Swansea tin plate industry 485

SWEDEN:

- Electric pig iron furnace in. Herlenius. *108
- Electric smelting of pig iron at Domperfvet. deGeer *429
- Crisis in tar industry 384
- Sweet. A new 64
- Switzerland:
 - Chemical industry of. Landoll. 21
- Synopsis of Recent Chemical and Metallurgical Literature. 33, 132, 224, 269, 313, 401, 620, 663, 706, 751, 850, 894, 1026, 1071, 1117.
- Syracuse Section, A. C. S.:
 - January meeting. 135

T

- Tanning:
 - Electro-osmotic process. (B. P.) 272
 - Process. (B. P.) 937
- Tanning extracts and materials:
 - Chestnut wood tannin Griffith. (N.) 1095
 - From *Acacia arabica* 988
 - From Australian shrub 181
 - Kongo trees as source of 337
 - Mfr. of extracts. Rialland. (B. P.) 984
 - Synthetic. Hill and Merryman. (N.) 1095
 - Synthetic. (B. P.) 984
 - Synthetic. (B. P.) 621
 - Tanning materials in Far East. Balderston. (N.) 1096

- Tariff:
 - Chemical schedule under consideration 181
 - Free list under consideration 318
 - Duty on potash asked 359
 - New tariff for camphor proposed 360
 - Hearings on phosphorus, ferromanganese and arsenic 403
 - Tariff prospects 533
 - Drafting of bill starts 580
 - Tariff asked for South's minerals 713
 - Opposes duty on iron pyrites 855
 - Two cent duty on sugar asked 856
 - Young opposes Longworth resolution 1030
 - Tariff on minerals. Pawl. 1002
 - Chemical industry from tariff viewpoint. DeLong. (N.) 712
 - Tariff schedules. Longworth. (N.) 824
 - Emergency tariff bill:
 - Knox dye amendment. 853
 - Passes Senate 897
 - Conferees agree on 941
 - Text of dye control title 985
- Tariff Commission:
 - Chemical industry and. DeLong. (N.) 712
 - Surveys of chemical industries 86
 - Burgess nominated for. 1157

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY:

- New York meeting:
 - Preliminary plans 185
 - Program 447
 - Report *726
- Executive committee meeting 900

- Temperature control for catalytic oxidation. Downs. (P.) *1027
- Temperature conversion tables. Comment. Holmes. 637
- Temperature recorder. Time-punch feature of 750
- Theoretical chemistry. Future developments of. Langmuir. 553
- Therapeutic value. A question of. Leech 548
- Thermal analysis by differential method. Gray. (S.) 225
- Thermocouples. Base metal. Calibrating. Marsh 1071
- Thioglycolates. (B. P.) 896
- Thorium salts. Mfr. of. Lindsay Light Co. (B. P.) 225
- Tidal power. British report on use of. 428
- Tinning pot scrap. Treatment of. Clegg. (B. P.) 134
- Tin:
 - Tariff problems 1003
- Tin plate industry in Swansea 485
- TNT not highly sensitive 1118
- Tower packing efficiencies. Jorgensen. *741
- Trade associations. Secretary Hoover on. 1076
- Trade marks used by export associations 856
- Tribenzyl phosphate in celluloid mfr. Stockelbach. (P.) 851
- Tungsten:
 - Metallic. Production at Keeler, Cal. 374
 - In 1920 757
 - Mfr. of. Head. (B. P.) *896
- Tungsten ores. Tariff problems 1005
- Turf. Hydroturf process for drying. 215

U

- Ultramarine. Mfr. of. Guimet. (B. P.) 315
- Union Bag & Paper Corp. plants closed. 986
- Units of volume and weight, and energy. Interconversion tables for. 434
- U. S. Fixed Nitrogen Corporation bill: (see under Nitrogen Fixation)
- Utah University fellowships in metallurgy 798

V

- Valve. Flow-regulating. For viscous liquids *268
- Vanadium:
 - Plant closed 491
 - Tariff problems 1005
- Vanilla production in Guadeloupe. 608
- Vegetable and fruit dehydration. Present status of. Cruess. *781

VEGETABLE OILS:

- Edible vegetable oil industry. Tefft. (S.) 894
- Treating cake from Baskerville process. Baskerville. (N.) 829
- Argentine industry 612
- Indian oil seeds 345
- Viscose. Mfr. of. Muller. (B. P.) 621
- Vulcanized fiber. Washing. Linder. (P.) 752

W

- Wages in New York chemical plants for Nov., 1920 360
- Wallace elected secretary, American Engineering Council *357
- War Minerals Relief Act administration. 1120
- Washington Chapter, A. S. S. T.:
 - April meeting. Molybdenum steel. 800
 - May meeting 968
- Washington Section, A. C. S.:
 - February meeting. Fertilizers. 359
 - May meeting. Optical methods 942
- Washington University fellowships. 854
- Wastes. Industrial:
 - American Engineering Council plans to eliminate 358
 - Progress of surveys 623
 - Report 1073
 - Recovery at Holland-St. Louis Sugar Co. plant 756
 - U. S. Industrial Waste Commission. 1157
- Water. Separating air from feed water. Hulsmeier. (B. P.) *1028
- Water purification:
 - Residual aluminum compounds in water filter effluents. Wolman and Hannan. *728
 - Discussion by Dr. Whipple. (N.) 1077
 - Lime in. Brown. (N.) 1142
 - Chlorine control apparatus for. Paterson. (B. P.) *1072

Water-softening:

- Comparison of various methods of. Taylor. 123
- Correction 252
- Comment. Booth. 284
- Comment. Yoder. *592
- Wave power transmission. 85
- Waxes:
 - Oils, fats and waxes in Latin America. Wilson *1101
- Weights and measures conference 856, 942
- Welding:
 - Long cast sections made by welding *268
 - Welding blow-holes in steel. Brearly. (S.) *1026
 - Phenomena of arc-welding. Escholz. (N.) 817
- Western Canada Pulp & Paper Co. enlarges 135
- Western Chemical and Metallurgical Field 374
- Western Chemicals, Inc., plant at Tonopah *529
- Weston standard cell. Abnormal behavior of. Mellon. 166
- Whitney, Willis R., Presentation of Perkin Medal to *99
- Wilcox Oil & Gas Corp. plans refinery at Wood River, Ill. 274
- Willard Gibbs Medal awarded to Mme. Curie. 713
- Presentation *1132
- Wilson dam: (see also Nitrogen Fixation: Government Plants)
- Hearings on continuation of 403
- Wisconsin University students to make organic chemicals 492
- Scholarship to France 1118

WOOD:

- Killing molds by steaming 924
- Microstructure of. Abrams. (N.) 834
- Moisture content of pulpwood. Rapid method for 964
- Waste. Yields of alcohol from. 212
- Coloring. Slade. (B. P.) 272

WOOD DISTILLATION:

- Illuminating and heating gas from. (S.) 132
- Application of Cottrell precipitator to. Hawley. (N.) 829
- Effect of adding chemicals previous to distillation. Hawley. (N.) 833
- Distillation of Missouri oaks 757
- Removing tar from pyroligneous liquors. Barbet. (P.) 752
- Wood pipe in chemical industry *32
- Wood posts for plant inclosures. 1070
- Wood preservation:
 - Sodium fluoride. (N.) 578
- Protection of piles in infested waters (N.) 578
- Industry in 1919 165
- Wool. Imitation:
 - From vegetable fibers. Soc. Gillet et Fils. (B. P.) 36

X

- X-Rays:
 - In industry. Shearer. (N.) 317
 - Analysis of crystals by *775

Y

- Yeast:
 - Edible yeast preparations. Plauson and Vielle. (B. P.) 937

Z

ZINC:

- Condensation of zinc vapor. Ravner *885
- Pulverizing. Miller. (B. P.) 37
- Electrolytic:
 - Anaconda Copper Mining Co. plant at Great Falls. *245
 - Discussion on 329
 - Analytical control of. Bradley. 461
 - English plants 884
 - Purification of solutions for. Peterson. (B. P.) 315
 - Removal of arsenic from zinc electrolyte. Hanley. *693
- Zinc dust. Nature of. Ravner *932
- Activating. (B. P.) 315
- Zinc nitride research. McCormack. (N.) 757
- Zinc ores. Sulphide. Treating. Mackay. (B. P.) 708
- Zinc oxide:
 - French process. Singmaster and Courson. (P.) *895
 - Mfr. of. McKee. (P.) 35
- Zinc pigments. Mfr. of. Clerc. (B. P.) 1028
- Zinc polysulphide. (B. P.) 896
- Zirconia cements. Sheppards. (N.) 421

*Illustrated; (P.), (B. P.)—United States and British patents respectively; (S.)—Synopsis; (N.)—Papers read at society meetings but not printed in full.

Number 1

Optimistic Outlook in The Chemical Industries

IN EXTENDING to the friends of CHEMICAL & METALLURGICAL ENGINEERING a cordial holiday greeting and sincere wish for a happy and prosperous New Year, the editors are not lightly repeating a perfunctory salutation. On the contrary, we are fully mindful of the serious industrial and economic problems which must be happily solved if our wish is to be consummated before Nineteen Hundred and Twenty-One slips away. With the year that has gone we need have little concern except to profit by its lessons. In many respects it was disappointing. It had a skyrocket career; and while a skyrocket in flight is an interesting spectacle until after it bursts in radiant splendor at the zenith, there is always the dull and uninteresting but inevitable accompaniment—the descent of the stick.

But it is with neither the rise of the rocket nor the descent of the stick that we salute our friends. Rather do we wish to greet them at the opening of the year with a note of optimism and confidence which we ourselves feel and which we have found in a remarkable degree pervading the chemical industries. Being somewhat curious as to the mental attitude of manufacturers in the chemical and allied industries under the industrial depression which has prevailed for some time, and wishing to discover at first hand what plans they were making for the future, when they expected a revival of business and how they felt about our chemical industries as a whole, we resorted to the useful questionnaire. The replies have been gratifying. If we had been suffering from depressed spirits, we would have been revived by the expressions of optimism and confidence in the future voiced by our correspondents. Seventy-five per cent of them were distinctly optimistic, and the balance noncommittal. The current industrial depression has been felt by only 60 per cent, although some who have not yet felt it admit the possibility of a slight lull early this year. It is noteworthy, however, that two-thirds of our friends have neither reduced their forces nor curtailed their outputs. In many instances they are running on accumulated orders which will require from two to four months for completion, thus tiding them over any temporary lull in business which may occur between now and spring. Such labor as is being dispensed with is mainly the unskilled variety, because manufacturers of engineering and technical equipment and apparatus realize the value of the skilled artisan and are preserving their organizations. As a consequence we may conclude that unemployment is not widespread in these industries. In some cases forces are being reduced in order to weed out the inefficient, and the beneficent influence of this process has already been observed in the attitude of the employee toward his job.

Speculation has been rife as to the time when we might look for normal resumption of business. Economists, industrial leaders, business men and the average citizen have all made their guesses. The matter is not altogether one of psychology, because time is required for the physical accomplishment of certain things. Curiously enough, the impression seems to be almost universal that late spring or early summer should witness the transition from depression to activity. This opinion is concurred in by our correspondents.

As to the factors which will influence a speedy return to normal conditions, there is remarkable unanimity of opinion that tariff legislation is of primary and vital importance. There is a marked tendency to place confidence in the lawmakers at Washington, as well as to impose upon them the necessity for hard work and exercise of brain power. Not a few are of the opinion that Congress must listen more and more to technical advisers. The feeling that a tariff on dyes, chemicals and apparatus is essential arises largely from the fact that many of these industries have a direct relation to national welfare. In the case of dyes particularly, the fact that other nations have already protected their domestic industry only adds to the necessity of prompt action here.

Next to tariff protection, improvement in methods of taxation is mentioned as a factor in the return to normal business conditions. Next, in the opinion of our friends, is the matter of foreign exchange. Those who have commodities for export find it difficult, if not impossible, to do business at current rates, while those who are manufacturing in competition with foreign countries feel that the United States will become a dumping ground for cheap imports as long as the inequality in exchange exists. A hopeful note is sounded in one instance by a correspondent who sees the buying power of the dollar increased as domestic prices fall so that it will more nearly equal its value in foreign markets. It is noteworthy that few referred to the necessity of reducing wages as a prerequisite to business prosperity. Evidently manufacturers are not concerned so much with what a man earns as what return he gives for his wage.

Not infrequently during the past few years the fundamental soundness of our chemical industry has been the subject of question and discussion. Consequently we were particularly anxious to get the opinion of manufacturers on this point. The gist of the matter as contained in replies to our questionnaire is that in general the chemical and allied industries are on a sound basis, both financially and technically. This is particularly true with the organizations having large resources in men and money, though it is recognized that some of the smaller organizations which have been overcapitalized and poorly manned are not likely to weather the

distress of this period of readjustment. This curious but fatal combination prevails: Poor technology is observed in those organizations which have not the financial means to withstand the present strain. As a consequence they will fall under severe competitive conditions. If the service which they performed during the war is still needed it will be supplied by the larger organizations, whereas if their product is relatively unimportant, small in quantity and low in value, it may not be manufactured here at all. In any event it is the general impression that American chemical industry will hold most of the advanced positions gained during the war, although tariff protection is considered necessary in some instances.

All of this bears directly upon the ability with which we can meet foreign competition and establish ourselves in a position of independence. It is quite evident that industrial independence can usually be achieved if the people are willing to pay the price. Already there is evidence of the fact that competition with German and other European products is actively threatening the existence of some of the industries which during the war we came to regard as vitally necessary to our national welfare. As an example we may cite a widely used scientific instrument for which domestic manufacturers are charging about seven times as much as the cost of an imported article of equal grade. With such a discrepancy of price there is but one inevitable result, because buyers will look first at the price. The general feeling, however, as reflected in the replies to our questionnaire, is that the United States has thoroughly established its independence in those chemical industries which are characterized by large-scale production. On the contrary, it is not felt that the manufacture of many specialties has been perfected to a sufficiently high degree to meet foreign competition. Of course, a basic factor in the whole matter is the difference in cost of labor at home and abroad which cannot be materially altered by technology or good business methods.

Scattered here and there throughout our correspondence we find a few points mentioned only incidentally which we believe worthy of further emphasis. It is quite evident that those manufacturers who serve a diversity of consumers are in a strategic position when a period of depression comes. This can be accomplished in two ways: Either by manufacturing a variety of products for different industries or, more fortunately, producing some one thing that is useful in a number of industries. In either case the demand for the products may also have a seasonal nature which will distribute business uniformly throughout the year.

One of the most hopeful aspects of business in the chemical and allied industries is the money-saving and waste-eliminating character of the service, equipment or process offered by manufacturers and engineers. This is responsible for more than a few of our correspondents stating that inquiry for their product is more brisk than for some time past and that the prospect for closing contracts is unusually good. In other words, those who are prepared to put our industries on a scientific basis find their services in demand in direct proportion with the necessity for reducing costs, saving wastes, or increasing output.

Considering all conditions, we may conclude that what is now needful is business courage and respect for fundamental economic principles. Time will be required for the operation of economic laws, and some

distress will follow as a consequence; but if we look at business over a five-year instead of a one-year period, we may find current losses more than counterbalanced by earlier gains. Attempts to forestall by artificial means the inevitable readjustment now going on, or failure to understand the reason for it, or stubborn refusal to yield to it will only delay the revival of business. Psychologic as well as economic forces are at work. The latter are outside the scope of our influence, but to the former we want to add our note of courage, confidence and optimism, supported in tangible form by the judgment and testimony of leaders in the chemical and allied industries. By giving a little thought even a short period of adversity can be turned to useful purposes.

A Noteworthy Year

In the Steel Market

THE steel trade is one that has a habit of breaking precedents and records. The changes occurring in the market have been likened to the view obtained in a kaleidoscope. It is not the changes that occurred in the steel market during 1920 that constitute the most noteworthy thing about the year, but the character of the market itself, with its flight of prices on the part of the independents and the even line maintained by the Steel Corporation. No steel manufacturer would have predicted what occurred, and none perhaps would have admitted the possibility of such a thing occurring. A few might have admitted the possibility, at the same time asserting that the actual event was so improbable as not to be worth considering.

It was at the end of 1919 that the independent steel makers as a whole were primed for a substantial advance in steel prices. Some had advanced their prices, but the appearance was that of charging premiums for early delivery and merely refraining from selling for later delivery at base prices. It was expected that the Steel Corporation would advance its prices, and when the corporation did not take the initiative it was thought that at any rate it would follow the independents on the up track. To many independents if not the majority the remarkable thing seemed to be, not that the independent market advanced, but that the Steel Corporation did not make advances.

It was not a case, however, of the independents abandoning an established philosophy, of holding prices steady. No similar conditions had obtained in the past. There was a new state of affairs in connection with which there were no precedents. It was the Industrial Board prices of March 21, 1919, to which the Steel Corporation adhered, and when those prices, representing the second reduction from the war control prices, were announced it was a common feeling among buyers of steel, and among not a few sellers, that the prices were on the whole too high. They were, as a matter of fact, shaded in the April and May following, and when eventually steel makers found that instead of its being necessary to let the whole market go down there was to be an opportunity to obtain higher prices for a time, it seemed natural enough to go while the going was good, or "make hay while the sun shines." There was a scarcity of steel, resulting from the iron and steel strike being followed closely by the bituminous coal strike, a temporary situation likely to be followed eventually by a collapse. There seemed to be no hope either of holding prices down at the time or of holding them up afterward.

One of the great difficulties of the situation was the lack of integration among some of the independents. Some steel producers must buy their pig iron, and many pig iron producers must buy their coke. The coke producer sought such profits as were obtainable, particularly when his coal had a very high market value, the amount of coal converted into merchant coke being scarcely more than the proverbial drop in the bucket when compared with the size of the coal trade as a whole. The merchant furnaceman sells more pig iron to foundries than to steel makers and could not be expected to hold down the price of steel-making pig iron. Some steel makers had to have high prices in order to meet their costs, and they could obtain the prices. Why should others not?

Profits were made, but production costs naturally rose, and a readjustment is already in progress. Costs cannot be reduced to the pre-war level, but various excrescences can be lopped off, and many have been already. Costs will now have to be regulated by selling prices, when formerly they were allowed to go where they would.

Making Plant Troubles

Pay Dividends

THE Cottrell precipitator for recovery of fume forms the classic example of making profits from what were previously regarded as wastes or public nuisances. Many industries have used this means of dust or fume recovery to their financial advantage as well as for the improvement of their reputation among their neighbors. Fire and explosion prevention has generally been regarded as a necessary but costly problem with which the chemical plant must deal. However, new methods for elimination of fire and dust or vapor explosions give promise of being profitable, as well as effective for their primary purpose. This is possible through the use of inert gas methods for control of combustible vapors and dusts.

One large industrial plant which had numerous fires and a few small explosions caused by mixtures of air with the vapor of the solvent used is affording a striking example of the advantage of this work. This company installed equipment for making an inert gas mixture—carbon dioxide and nitrogen as the purified product of fuel combustion being the gas employed. This inert mixture carries off the vapor from the process, the solvent is absorbed from the gas by an oil-scrubbing process similar to that used for recovery of toluene from city gas, and the solvent is thus recovered. The result is safe and uninterrupted operation at very low cost and even this small cost is more than offset by the financial advantage through the solvent reclaimed. It is reported that this solvent costs about four cents a gallon instead of approximately thirty cents for new material.

There are many other industries using solvents under conditions that make explosion and fire hazard serious. The fire insurance interests have long since done their best to enforce care in these matters and have in many cases made it financially profitable to eliminate the principal hazard by largely increasing the insurance rates where the plant was not operated with maximum of safety. If one may add to this insurance saving the actual income from recovered solvents, there is certainly no longer an excuse for continuance of these dangerous plant practices.

Dyes, World Peace,

And Chemical Disarmament

AFTER much controversy, during which it came dangerously near muddling the whole matter, the British Government has adopted a definite policy with relation to its dye industry. Parliament saved the industry at the eleventh hour by passing a regulatory bill, the text of which is printed elsewhere in this issue. In its principal features it prohibits, subject to a licensing system, the importation of synthetic organic dyes and intermediates used in their manufacture. The Board of Trade is constituted the licensing authority, supplemented by an advisory committee composed of manufacturers and consumers. The provisions of the bill are to apply for ten years and no longer, at the end of which time it is confidently expected that the British dye industry will be able to stand alone.

England's action holds a salutary lesson for the United States which the present Senate will do well to consider. Conditions in the two countries prior to England's recent action were almost identical. Neither nation had a well-developed, independent dye industry, both being large consumers of the German product. By the same token both nations were helpless in the early stages of gas warfare during the late conflict. Following the Armistice both nations regulated the importations of German dyes, and England announces her intention of supporting a domestic dye industry. Subsequently the famous Sankey judgment destroyed the government's authority to regulate dye imports, and as a consequence the industry was in a perilous position until the new dye bill was passed by Parliament late in December.

Our own position in respect to post-war regulation is still satisfactory, but should peace with Germany be declared prior to the passage of the Longworth dye bill by the Senate, the licensing authority of the War Trade Board Section of the State Department would be abrogated and the way would be open for unrestricted importation of German dyes. It is this critical situation which makes it incumbent upon this Senate to agree upon a measure which will protect the domestic dye industry and permit it to develop to a state of independence.

The necessity for protection of the dye industry until it can stand alone is not wholly an industrial and economic matter. Its relation to world peace is closer than is suspected at first glance. One of the steps advocated in the interest of world peace is international disarmament, but thus far the advocates of such a measure have considered physical disarmament only and have strangely neglected the greater necessity for chemical disarmament. The latter is practically impossible as long as any nation holds a world monopoly in the manufacture and distribution of synthetic coal-tar products. No thoughtful reader can peruse V. LEFEBURE's article, published on another page, without being forcibly struck with the author's logical reasoning on this subject. We commend it to the earnest consideration of our lawmakers and shall see to it that they have an opportunity to read it. It is immaterial whether LEFEBURE's complete scheme can be carried out at the present time, but it is of vital importance to recognize the fact that the United States, as well as the other leading nations of the earth, must have an independent dye industry, in the interest of chemical disarmament and world peace, if for no other reason.

Mechanical Training

For the Industrial Chemist

THE average chemist is essentially a theoretical man and without knowledge of mechanical matters, but he must acquire such information as will enable him to direct them to his purposes. The lack of the simplest knowledge of mechanics and construction details among chemists is deplorable. Instances may be cited.

A highly trained chemist, more through good fortune to himself than judgment on the part of his superiors, had secured an operating position with the responsibility, among other heavy charges, of starting the equipment in an enormous new manufacturing plant. He knew nothing about the simple need of sweating in a bearing and at first refused to run the machinery idle, preferring to wait until the material commenced to come through. He insisted that a simple turnover of a few minutes proved the readiness of the machines to handle the load. Finally, however, under the threat of dismissal from the staff chemical engineer, who had mechanical training, he was persuaded to start up without load. It developed during the three weeks' tune-up that none of the equipment was ready, that bearings burned out, shafts had to be re-aligned and in two instances entire change in design was necessary. Had these breakdowns occurred under load several months' delay would have been inevitable.

But one might say, "Call in the mechanical engineer." Unfortunately he is not always available. The mechanical engineer with a knowledge of chemical plants is, moreover, a *rara avis*. Two instances will illustrate.

A large number of steel containers designed to hold a poisonous gas under pressure were put in by mechanics. These had been pressure-tested at the factory but traveled a long distance in coming to the plant. The chemical engineer, much to the disgust of the mechanical engineer, insisted on a second test in place. He knew that leakage of the gas would suffocate the workmen in the whole plant and cause expensive shut-downs. Finally, he had his way, and on putting each under a 500-lb. hydraulic test—accomplished inexpensively with a hand pump—water spurted forth from the seams and even from the sides of the steel vessels. These leaks were soon stopped by oxy-acetylene torch and calking with a cold chisel. Many thousands of dollars and vexatious delays were saved. The risk to human life was reduced to nothing.

A Gay-Lussac acid tower stood on four brick piers erected with the footing in sand of an old river bed. Evidently two of them were located over decayed matter beneath the surface, for one day they suddenly sank several inches, tilting the structure to a dangerous angle. The manager called in a construction company to quote on straightening up the work. It returned an estimate of about \$2,000. In the meantime a practical chemical-engineer foreman asked for a chance to try before the construction company was retained and received permission from the manager.

He requisitioned two ordinary two-man timber saws from the storehouse and called in four workmen. They proceeded to saw out two courses of brickwork and mortar on each of the two high piers, working around the pier until at last a slim support of material was left in the center of each. Mortar was thrown into the spaces, the remaining material was chipped out and the tower settled back to the vertical, where it has since been standing for several years.

This chap knew that of all tools available to the industries there are very few for putting on material, most of them being "taking-off" tools, and he simply saw it was easier to saw off a leg than to put one on. This is not chemical engineering, but common sense, which carries men far in business, chemical engineers included.

Gossiping Tongues

Injure the Profession

SOME time ago we heard a veritable tale of woe in regard to a commercial laboratory in good standing. The "kicker" declared himself to have been robbed by it of large sums of money, and to have been involved in a great waste of time with no results and, as he believed, no genuine effort to show for it. The man was not a chemist, but he talked with fervor, and his bitterness aroused our curiosity inasmuch as we knew the consulting chemist against whom the complaint was directed to be scrupulously careful, very competent in science, rich in technological experience, and a man of honor. So we proceeded with a little investigation of our own, and found three chemical laboratories involved instead of one—a little fact that was not related by the complainant and which the three chemists themselves did not know. We shall designate them as A, B, and C respectively. It was B who was the butt of the manufacturer's diatribe on the occasion in question.

What happened was that A was retained to develop a process, which he did. He did not finish his work, having carried it only to the initial stage. Then Mr. Manufacturer went to B without telling him anything of A and consulted him in regard to the process of which he declared he had made an initial instalment. B took the matter up where A had left it, and designated the necessary steps to carry it to completion. For this B charged a fee of \$75 and \$6.32 traveling expenses. Considerable correspondence of a friendly nature ensued for which no charge was made, which related to what the manufacturer would do when he had his complete apparatus installed. Without purchasing the apparatus at all Mr. Manufacturer then went to C, and how C is coming along with him we do not know, but we can guess.

All three are competent men; any one of them could have developed the process and carried it through to profitable operation; but the pig-headed manufacturer cannot understand chemical consequences; he does not know the difference between work in glass and in iron, he takes his chemistry as a lot of yokels take patent medicines, and the only so-called "reason" to which he will listen must emanate from men as ignorant of chemistry as he.

What is needed is less destructive gossip and more co-operation among consulting chemists. There is no profit whatever in letting ignorant men engage in loose and libelous talk about the vain things which they imagine. A few libel suits would do no harm in this respect. When a man begins to libel a brother chemist it is a good thing to make him give facts and figures, and then to send this record in to the man against whom the complaint is made. We do not want to put anything in the way of men of affairs seeking advice and counsel where they desire to get it; but we should like to see a halt called to malicious gossip. There is too much of it going on that has no foundation in fact, and that has its origin in crass and sour ignorance. It injures the whole profession.

Chemical Disarmament

The Author Passes in Review the Chemical Armament Implied in Chemical Warfare and Shows That the Crux of All Chemical Disarmament Must Be an Internationally Legalized Redistribution of Organic Chemical Producing Capacity Throughout the World

By V. LEFEBURE

WHAT is the present disarmament situation? Chemical disarmament is the crux of all disarmament.

The League of Nations, representing most of the nationalities, with the notable exceptions of America, Germany and Russia, has instituted a definite commission to consider the question of world disarmament. Of the above exceptions acute interest must be attached to the American attitude. The initiative for any new disarmament schemes, an essential backing of any such schemes already before the world, must come from America with special weight. We may safely assume that in the block of nations represented by the League there is a desire for peace and any measures which can insure it. No doubt can exist that this feeling is common to America. On this common ground, therefore, all parties, whether associated with or hostile to the League, must welcome any new light on the critical disarmament situation.

A brief analysis of armament reveals the fact that disarmament must cover three essential factors in warfare—the combatants, mechanical types of armament and war chemicals. Mechanical armament covers all projectile-throwing weapons, or projectors as we will call them, tanks, aircraft, appliances for transportation, warships, etc.

CHEMICAL ARMAMENT

Chemical armament, very generally, represents the actual death-dealing constituents of projectiles. This must, however, be qualified by the statement that although all pre-war chemical armament—that is to say, explosives—required a special projectile to convey it to the enemy—that is to say, was dependent on a shell—the new type of chemical armament has become in some cases and may increasingly become independent of any special projectile. This is a most important item from the point of view of disarmament. It means that the limitation of projectiles may not carry with it limitation of the chemical weapon.

It is fairly safe to assume that any world organization devising disarmament schemes could cover with a fair degree of certainty the first two forms—that is, the combatant and the mechanical type of warfare. It can be claimed that the component parts of mechanical armament can be produced rapidly in easily-converted peace-time factories. This applies, for example, to machine-gun parts; but all of these weapons, if produced in quantity, necessitate huge assembly plants, and these without doubt can be subjected to inspection and control.

But how do normal disarmament schemes apply to

the chemical type? This type of weapon covers, roughly, two classes—explosives and the so-called poison gases. Now we must at once correct any false impression as to the relative importance of these two sections of chemical armament. The recent war has witnessed a gradual change in this matter. Explosives which at the commencement of the war represented nearly 100 per cent of all projectile fillings can no longer claim more than 50 per cent of that capacity. This can be substantiated in many ways. It is sufficient, however, to point to the fact that in the last great German retreat their huge ammunition dumps which we captured contained at least and in many cases more than 50 per cent of shell which were filled not with explosives but with the other type of war chemical, commonly called poison gas. There is no doubt that another year of war would have seen this percentage greatly increased.

CONVERTIBILITY OF DYE PLANTS FOR POISON GAS PRODUCTION

Pursuing our analysis, we must face the following question: Is there any essential difference in the disarmament aspect of explosives and the other types of war chemical? They have one common characteristic. This is their peace-time use. This refuses to any disarmament scheme the right to disarm in the simplest fashion—that is, by the total destruction of producing capacity. The world must have for normal development a large producing capacity for explosives and for the other types of chemical armament. This is self-evident for explosives, but may not be so for poison gas. We can readily establish the point, however, that the poison gas or chemical warfare campaign was initiated, fostered and most thoroughly exploited by Germany of all the belligerents. This country produced practically every ounce of her hundreds of thousands of tons of poison gas in dye plants, in dye factories. The examination of German gas production leaves no doubt whatever that the infinitely flexible, almost instantaneously converted dye plants are a logical means of production of all organic chemical weapons, including explosives.

FACTS TO BE CONSIDERED IN CONNECTION WITH CHEMICAL DISARMAMENT

We must now stop to lay emphasis on a general principle. There are two methods of disarmament. In the first class you can disarm very simply by destroying all the means of production and preventing their renewed growth. In the second class, because the means of production—the factories—have a peace-time function, you cannot disarm by destruction. How then can you disarm in this case?

There is only one way—it is to insure that no one country possesses a monopoly in the means of produc-

EDITOR'S NOTE—The author was British liaison officer with the French forces from the inception of chemical warfare until after the Peace Conference and is especially qualified to speak with authority on this subject.

tion. The brightest and most telling war chemical invention has no value for and no incidence upon warfare unless it can be produced rapidly and in quantity. Production is the key to its war use. Let us examine very briefly, therefore, the world distribution of the means of production for this new type of weapon. The facts are too well known to demand more than a brief reference. Before the war Germany held the almost absolute monopoly of world organic chemical production. Through this monopoly she launched the poison gas campaign, and for more than two years the Allied reply was relatively feeble. This was not due to Allied lack of invention, but to lack of producing capacity. Production occurred in improvised plants which weakened Allied resources and, most important of all, introduced no essential change in the German monopoly position.

During the war, however, for economic rather than military reasons, dye-producing industries sprang up in France, America and England. Their development was relatively feeble, owing to numerous obvious reasons. They could not make their just demand upon the research forces of the countries concerned. The erection of the plants suffered at the expense of the other great munitions industries which were developing, and in some cases as soon as a plant was erected the dire needs of the situation diverted its production from that of dyes to that of explosives and other organic chemicals. From the point of view of our argument this development left the world in the following situation regarding organic chemical producing capacity:

The German dye industry, the source of her war chemical production, was considerably strengthened. She had a world monopoly before the war, and in every way from the point of view of production, research forces, government support, etc., she was strengthened by the war in her bid for post-war world monopoly. Other countries than Germany were left with promising but relatively feeble organic chemical resources which could not immediately, even under normal commercial conditions, hope to break the German monopoly. In other words, although for most types of armament the pre-war balance in favor of Germany was decreased, yet for this one type of chemical armament the German monopoly was strengthened.

WHAT THE GERMAN ORGANIC CHEMICAL MONOPOLY IMPLIES

We are, therefore, left in face of the following situation: For most types of armament the war has led to a redistribution of producing capacity in the direction of an equilibrium. We can reasonably hope, by materially diminishing this capacity and suitably controlling and inspecting it, to obtain international disarmament; but in one particular, in chemical warfare, for which the means of production is organic chemical capacity, the final situation is just as remote from any equilibrium as it was before the war. Now we cannot, for the reasons already given, urge the complete destruction of the German producing capacity. On the other hand, disarmament in all other weapons will leave the war importance of chemical warfare greatly enhanced.

The conclusion is obvious. The world must have organic chemical producing capacity, but it cannot tolerate a monopoly of that capacity, especially if that monopoly be held by those who so drastically abused its possession. There must be a redistribution of organic chemical producing capacity throughout the world before we can claim to have even approached

disarmament. It would be farcical to proceed with general disarmament schemes and to leave untouched this monopoly in chemical armament. It can, therefore, be claimed without any exaggeration that the chief question before those who wish to see the world on a peace footing is the redistribution of this capacity throughout the world. In other words—and to ignore this issue is dangerous—we must break the German organic chemical monopoly.

How can this be achieved? There are two main avenues of approach. The new-born dye industries of France, America and England, and if you wish, other countries, must be supported nationally through legislation, and internationally through some such organization as the League of Nations; or, for those who oppose the latter, support must come on the common grounds of disarmament toward stable world peace.

INTERNATIONAL MEASURES NEEDED TO REGULATE CHEMICAL DISARMAMENT

In America and England legislation designed to protect the dye industry is before both countries. The issue is likely to be fought out on purely national grounds. This alone is entirely unsatisfactory. It must be realized by all concerned that they are legislating on a matter which has infinitely more than commercial significance. They are legislating on world peace. If that be so, they deserve the active support of those whose chief business is the promotion of this peace by definite international measures. From this point of view it is imperative that in France and England the League of Nations representatives should bring the matter strongly to the notice of the League of Nations, where it should be dealt with by their special Disarmament Commission. America can be a strong factor in this connection. A recent request has been made by the League for the appointment of an American representative to attend the disarmament conferences at Geneva. Although America is not a member of the League, and even if she be hostile to it, this representative will have great weight in these conferences.

Chemical disarmament is a matter which, unfortunately, non-technical people do not fully understand. They think it sufficient to issue an edict against the use of poison gas, not realizing that this alone is absolutely futile as an effective measure. You cannot prevent any discoveries in chemical warfare, because, unlike the development of mechanical invention, such chemical discoveries can occur, when directed by a trained mind, with the mere use of a few pots, pans, beakers, in any unguarded and unsuspected locality. The redistribution of producing capacity is therefore critical. It is, therefore, very important from the point of view of disarmament that any American representative proceeding to Geneva should have a clear view of the fundamental principles of chemical disarmament and make strong representations on this matter.

A LEAGUE OF NATIONS OUGHT TO STUDY THE REDISTRIBUTION OF THE WORLD DYE INDUSTRY

The present League or any league cannot fairly demand and expect a satisfactory answer to its request that governments should cease to support chemical warfare research and chemical military establishments unless that league be ready to support in its turn the essential chemical disarmament measure—that is, the redistribution of the world dye industry and the break-

ing of the German monopoly. From another point of view, essential action has been neglected on this matter and should be taken up again by the League of Nations, by those making representations to it or having any weight with it, by those responsible for the execution of the Treaty of Versailles and by America in any new treaty which she may make with Germany.

Articles 168 and 169 of the Treaty of Versailles are specially concerned. The former provides for the restriction by the Allied and Associated Powers of the manufacture of war material and of the approval of those Powers for the continued existence of factories and works for such production in Germany. On these grounds it is logically possible to limit seriously that capacity of the German dye industry which produced poison gases during the war and may continue to do so. Article 169 provides for the surrender to the Allied and Associated Powers of any special plant intended for the manufacture of military material, except such as may be recognized as necessary for equipping the authorized

strength of the German army. The execution of this clause, if a proper interpretation of chemical armament be used, would imply the closing down of many of the German dye plants which produced those huge quantities of poison gases during the war.

We repeat that the crux of all disarmament is the redistribution of organic chemical capacity throughout the world, and that, interpreted into action, this implies the serious reduction of the producing capacity of the German dye monopoly and the international support by the League of Nations, or any other similar bodies which may be established, of the legislative measures about to be brought before such countries as America and England for the protection of the growing dye industries, replacing the reduced German dye-producing capacity in those two countries. This is, without any doubt, one of the most important measures now before the world and in addition one of the few measures with regard to which immediate action can be taken toward the stabilization of world peace.

Election of Officers and Directors of the Allied Chemical & Dye Corporation and Subsidiaries

Personnel of the Allied Board—New Interlocking Directorate Elected by Barrett and National Aniline Companies—Changes to Make Boards of Active Executives

AT THE organization meeting of the Allied Chemical & Dye Corporation, Dec. 21, the following directors were elected:

Chairman of Board, Dr. W. H. Nichols of General Chemical
President, O. F. Weber, National Aniline

Vice-presidents, H. H. S. Handy, Semet-Solvay

W. H. Childs, Barrett

E. L. Pierce, Solvay Process

W. H. Nichols, Jr., General Chemical

Secretary-treasurer, C. S. Lutkins, General Chemical

Assistant secretary-treasurer, T. E. Casey, Barrett

The Barrett Trail for January comments as follows on the chief executives of the Allied corporation and the new directorate of The Barrett Company:

"In Dr. Nichols, this great corporation has a worthy chairman, a man who has given fifty years of his busy life to service in a field in which he is still active; a man—it is not exaggeration to say it—who brought an industry into being, nursed it through infancy, endowed it with the dreams of boyhood, the ambition and strength of manhood, the foresight and wisdom of maturity, and who now sees the fruition of all his hopes and expectations from his post of high honor.

"One need not look far to realize what manner of man is Dr. Nichols. President of the American Chemical Society, in which he holds charter membership; president of the Society of Chemical Industry, president of the Eighth International Congress of Applied Chemistry—he has had every mark of distinction his contemporaries can give him. The Allied corporation is indeed fortunate in having such a man as its chairman.

"Orlando F. Weber brings to the presidency of the corporation every quality necessary for the successful conduct of its affairs. Leader in and organizer of America's dyestuff industry, he is peculiarly fitted to take up the tasks that await him.

"The first board of directors of the Allied corporation consists of the following men:

"W. H. Nichols, Sr., chairman; W. H. Nichols, Jr., E. L. Pierce, H. H. S. Handy, Eversley Childs, William Hamlin Childs, O. F. Weber, W. J. Matheson, Rowland Hazard, Armand Solvay, Roscoe Brunner, Emanuel Janssen.

DIRECTORATE CHANGES IN BARRETT CO.

"At a special meeting of the board of directors, held Dec. 17, Eversley Childs, chairman of our board of directors, and William Hamlin Childs, president of the company, tendered their resignations, coincident with the incorporation and organization of the Allied Chemical & Dye Corporation.

"Vice-President W. N. McIlravy was elected to succeed Eversley Childs, and Vice-President and General Manager T. M. Rianhard was elected to succeed William Hamlin Childs, who was made chairman of the executive committee.

"As was true of the retiring heads of the company, their successors are men who have been identified with the coal-tar industry—and therefore with The Barrett Co. or its predecessors—all their lives. Mr. McIlravy was associated with Mr. Childs in the Mica Roofing Co. practically from the start. Mr. Rianhard came to the company by way of the Warren Chemical & Manufacturing Co.

"At the same meeting, ten of the members of the board of directors resigned and eight men were elected to replace them. Those resigning were as follows: H. W. Croft, president Harbison-Walker Refractories Co., Pittsburgh; J. H. Fulton, vice-president National City Bank, New York; W. S. Gray, president William S. Gray & Co., New York; Dr. A. C. Humphreys, president

Stevens Institute of Technology, Castle Point; I. B. Johnson, vice-president Isaac B. Johnson & Co., New York; Powell Stackhouse, director Cambria Steel Co., Philadelphia; Hamilton Stewart, vice-president Harbison-Walker Refractories Co., Pittsburgh; J. H. Staats, New York; H. D. Walbridge, H. D. Walbridge & Co., New York, and H. S. Wilkinson, chairman Crucible Steel Co., Pittsburgh.

"The new members of the board include the presidents of three of the merging companies and five Barrett men, to whom, as with Mr. McIlravy and Mr. Rianhardt, their honors come as fitting recognition of years of loyal and efficient service.

"E. L. Pierce, president of the Solvay Process Co.; W. H. Nichols, Jr., president of the General Chemical Co., and Orlando F. Weber, president of the National

the Barrett Manufacturing Co. in 1902 as office manager. On Feb. 10, 1903, he was elected assistant secretary and assistant treasurer, and on Jan. 25, 1911, became secretary and treasurer of the company.

"D. W. Jayne, manager of our chemical department, began his connection with our company when he joined the department in November, 1902, assisting the superintendent at the Frankford plant. He was appointed assistant manager in 1907 at the time the office of the chemical department was moved from Grays Ferry to Frankford. Upon his father's death, in 1910, Mr. Jayne was appointed to succeed him as manager, and has continued in that capacity to the present time.

"Clark McKercher was a member of the United States Department of Justice before coming to the company in 1913. He has been our general counsel for seven years."

T. M. RIANHARD

Aniline & Chemical Co., together with H. H. S. Handy, president of the Semet-Solvay Co., who for some time has been a director, give representation to each of the other merger companies on our board.

"The five Barrett men elected to the directorate are well known to the Barrett organization.

"W. B. Harris is our general sales manager. He began his long service in 1896, when he joined the Mica Roofing Co., and later became salesman for the National Coal Tar Co. He next was associated with Mr. Rianhardt in the Warren Chemical & Manufacturing Co., finally becoming its general manager. In January, 1913, Mr. Harris was appointed manager at Birmingham, and in December of the same year he became Mr. Rianhardt's assistant in New York, later taking up his present duties.

"M. H. Phillips, manager of the New York branch of the company, has one of the longest if not the longest service record among our active employees, a brief account of which appears elsewhere in this issue in connection with the occurrence of Mr. Phillips' thirtieth Barrett birthday, Nov. 19.

"E. J. Steer is our secretary and treasurer. He joined

W. N. McILRAVY

At a meeting of the board of directors of National Aniline & Chemical Co., Inc., held Dec. 21, Orlando F. Weber offered his resignation as president. J. W. Newlean was elected president of the company and Mr. Weber continues as chairman of the board of directors.

F. M. Peters resigned from the board and E. L. Pierce, president Solvay Process Co., was elected a director. B. A. Ludwig, C. F. Weber and Dr. L. H. Cone were elected vice-presidents of the company.

Judge Gary Sees Prosperity Ahead

Judge Elbert H. Gary, chairman of the board of the Steel Corporation, in a recent interview with newspaper men, reiterated his faith in the prosperity of the United States. He held the war responsible in great part for present economic conditions, but said that capital is also responsible in some measure, due to its use of "unreasonably, if not unfairly" increased fortunes.

Despite all these conditions and the alarmist views held by some, Judge Gary affirmed that prosperity is coming, just when he could not say, but surely coming.

THE OUTLOOK FOR THE FERTILIZER INDUSTRY

A Broad View of Both the Consumption and the Production Side of the Fertilizer Situation — Industrial Agriculture and Professional Farmers—Expansion in the Western States—
Inoculated Sulphur—Phosphate Rock—Potash and Nitrogen

BY FRANK K. CAMERON

THE present status of the fertilizer industry is very favorable and the outlook is, on the whole, as alluring as for any other industry in the country. The fundamental needs of civilized man are food and clothes. Food and clothes are directly dependent on the management of the soil. In the conditions of society which have developed in the United States, cultivation of crop plants and therefore management of the soil imperatively must be far more intensive than hitherto. Of the primary instrumentations for these purposes, that which is most directly under man's control and susceptible of modification is the use of fertilizers; and fertilizers, to be economically used, must be manufactured or prepared for the user. Hence the industry is on a firm, sound, fundamental basis of universal human need.

The industry now possesses the public confidence. This is its greatest asset. It is worth while to accent the fact, for it has not always been the case. It is not proposed to discuss the mistakes of the past, for this is not a historical retrospect, but to attempt to analyze and visualize the present and immediate future. The reasons for the present gratifying relation of the industry to the public are many. Only a few of the more salient can be recounted within reasonable limits for a magazine article. Undoubtedly, the services of the industry during the war, especially that rendered by many of its prominent personnel, and in turning over sulphuric acid and other plant equipment to munition production, have been potent factors. But perhaps rather more or less consciously the industry has undergone a revolution during the war years and the succeeding period. Many of the changes were initiated before the war, it is true, but were hastened to actualities under its stress. We are only concerned, however, with the results and not their history.

In this day and generation, in the United States the old time-honored concept of farming is rapidly disappearing, being replaced by a recognition of a consid-

erable group of agricultural industries or distinct businesses, some of them very highly specialized, with highly developed technology, served by a highly trained corps of professional advisers with the same type of cultural training called for in the engineer, lawyer or physician, and requiring skilled labor. In fact the unskilled laborer is relatively of no more value today in farming occupations than in the mechanical industries or factory operations. Yokels do exist, it is true. So do cobblers. Both have their fields of usefulness as yet, but the one is of no more significance in American farming than is the other in the boot and shoe industry.

The fertilizer industry in the United States, now recognizing the average American farmer in his true aspect, is rapidly reorganizing to give him the service he requires. The older propaganda, deliberately founded on ignorance and prejudice and involving an enormous multiplicity of brand names regarded as the pride but really the curse of the industry, has been abandoned, the end hastened or forced by the inability of the manufacturers to obtain the necessary supplies of raw materials during the war. Most fortunately they have been replaced by a limited number of standard mixtures recognized by the trade as a whole and by state and federal agricultural authorities as well. And the industry has founded and supports soil improvement associations officered by highly trained specialists who, co-operating with other recognized authorities, public and private, truly and conscientiously endeavor to determine the needs of the individual or the community and, so far as the industry can, to supply these needs. In other words, the industry recognizes that true service pays better than merely pushing a brand name, and is profiting thereby. Again, the war conditions in this country brought the farmers generally a command of cash credit, enabling them to escape from the pernicious practice of purchasing their fertilizer on deferred credits based on crops yet to be

LOADING POTASH SALTS DEPOSITED FROM BRINE AT SALDURO, UTAH

planted, and at the same time enabled the industry to reorganize its selling methods so as to avoid as much as possible a resumption of this economically unsound system.

EXPANSION IN THE WESTERN STATES

Within recent months well-founded rumors have been current that factories for the production of commercial fertilizers are to be erected in Kansas City, in Sioux City, perhaps in Denver and Salt Lake City, and several new plants are definitely planned for the Pacific Coast. Recent tests in the intermountain regions by disinterested observers have shown that commercial fertilizers have markedly favorable results with sugar beets, canning crops and alfalfa. Even more remarkable, because unexpected, are preliminary reports on the use of fertilizers in dry land agriculture where the crops are small grains. Quite significant are the quite numerous inquiries for fertilizers during the past two years by farmers on Western lands, and the interest in them manifestly developing in the Dakotas, Colorado, Utah, Oregon and Washington will surely crystallize into active demands as soon as there is a reasonable prospect of the demands being met at reasonable cost figures. Credible observers in the business estimate that together with California they will probably require 150,000 tons of phosphate rock the coming year, and potash and nitrogen carriers in proportion. A noteworthy development in California is the long staple cotton. This year there are reported to be more than 400,000 acres planted to this high-priced crop in California, Arizona and New Mexico, and experimental acres throughout a large part of the San Joaquin Valley have proved uniformly successful, so that a very largely increased acreage is to be expected next year. In fact, this type of cotton promises soon to rank with citrus fruits in importance in California. Many planters from the Southern States are being attracted, men thoroughly imbued with the knowledge of the value of fertilizers in cotton culture, and a large market in that area seems assured. Therefore a much extended use with other crops, as familiarity of the community with fertilizers increases, seems very probable.

The supply of raw materials is the chief specter on the horizon, but only because of the difficulties of bringing them to the plant, for in amount they appear illimitable and of sufficiently diversified origin to pre-

clude any long-continued stoppage. The market demands are insistent and greater than the prospective production. So far as anyone can now intelligently guess the future, this condition is to prevail, so that ready sales and good prices seem assured for many seasons ahead.

INOCULATED SULPHUR

While the most striking feature of the present situation is the remarkable and happy reversal of public sentiment toward the fertilizer business, and the general improvement in the technology of the manufacturing operations is not much less striking, it must not be lost to sight that a third development has assumed very great importance in the immediate past—namely, a sympathetic consideration of possible new fertilizers and new forms of older established constituents.

Of the new proposals, attention must be called to sulphur. That sulphur might have an importance as a fertilizer has often been suggested, but these suggestions have been sporadic and commanded no general attention until Lipman's experiments with sulphuric acid in California. O'Gara's observations in connection with his investigations of the effects of smelter fumes on soils and vegetation and those of the Oregon State Experiment Station served to excite interest in the value of different forms of sulphur carriers and to prepare the public mind for the announcements of the elder Lipman at New Brunswick, who has shown what others had suspected but left for him to find the proof—that the value of elemental sulphur and presumably of combined sulphur is probably dependent upon the presence of particular bacterial organisms, and that these organisms are most efficient when other particular substances are present in desirable amounts such as organic debris and basic phosphates of lime.

These investigations have led to patented processes, and it is reported that one of the large sulphur producers in the Gulf fields expects to put on the market in the near future a mixture of elemental sulphur, phosphate rock and suitable organic matter impregnated by special strains of bacteria artificially bred to extraordinary efficiency in making effective the mixture when applied to the soil. There has been accumulated a sufficient body of apparently irrefutable evidence in the near past to make it appear that sulphur in various forms is sometimes very valuable as fertilizer on some

soils and with certain crops. As to how generally it may profitably be used probably no one knows today. Serious and capable technical studies are under way, supported by adequate commercial backing, and the interested public will in due time be properly advised as to the value of the new fertilizer.

CONCENTRATED FERTILIZER

For years, particularly by the Federal Bureau of Soils, attention was called to the necessity of considering the use of more condensed forms of fertilizers than those in common use. The continued rise in freight rates and in the costs of farm labor were the potent arguments, although there were others which appealed but little less strongly to the technically minded man. Uniformly, the foremost manufacturers of "complete fertilizers" took the ground that they favored higher grade goods than were then on the market, although their actual output did not lend much credit to this statement. But quite uniformly they always opposed putting mixtures of pure salts on the market by the statement that the farmer wished only the goods diluted with "filler" because he possessed neither the machinery nor the wits to devise means of distributing the very high-grade or pure salt mixes.

Times have changed. At least they are changing. *Double* superphosphates are on the market and are bought eagerly. A long step further, ammonium phosphates are in the fertilizer market and it is not a wild surmise that a few years hence will see most of the phosphorus marketed in this form. Eighty or 90 per cent potassium chloride is eagerly absorbed by the fertilizer trade when it can be obtained. Two of the largest chemical manufacturers in the country, it is reported, have made a combination which will put on the market during the coming year an enormous tonnage of ammonium chlorides, which they expect to be absorbed by the fertilizer trade on the ground that it contains a higher percentage of "available" nitrogen than any other compound made in sufficient quantity to use as a fertilizer.

SULPHURIC ACID

The aggregate production of sulphuric acid is probably now greater than 6,000,000 tons, calculated to a 50-deg. Bé. basis. If one is to credit all the current reports, this production will be greatly increased in 1921, for war stock accumulations will have totally disappeared by then, and there is to be a much increased production of phosphate rock, which will call for an increased production of acid to convert it into more soluble phosphates.

Certainly there have been erected some new and large sized plants, and others are more or less definitely promised in the near future, especially on the Pacific Coast. There are several large plants, notably those connected with the zinc smelters of the Middle West, which were practically completed when the armistice brought a sudden halt to munition manufacture, but which have not yet been put in operation.

The development of the Louisiana and Texas sulphur mines has been followed by an increasing use of this material in making sulphuric acid. Just what proportion of the acid produced in the country is from this origin is not definitely known as yet, but it is certainly large and probably will remain large. The domestic consumption of sulphur is approximately 875,000 tons. How much is used for making insecticides and products

other than sulphuric acid seems not to be known definitely, but the bulk of the production goes into the manufacture of the acid. Probably 50 to 60 per cent of the sulphuric acid now going on the market is made wholly or in part from elemental sulphur. On the average the acid now produced is better than hitherto. Another feature of the present development is that a very much larger proportion of the acid made now is in the form of 60 deg. Bé. or stronger, because it must be shipped in tank cars to the mixing plant. Increased skill in the handling and mixing with rock has resulted.

PHOSPHATE ROCK

In the United States the use of bones, basic slag, etc., is too limited to have any particular significance for the industry as a whole. The chief sources of supply for the phosphate of fertilizers are the rock deposits of Florida, Tennessee, the Western field and perhaps Charleston.

Florida easily holds the first place. It produced about a million and a half tons in 1919, or less than half the tonnage for 1913. The production was considerably curtailed by strikes and transportation difficulties, and of course exports were greatly reduced. If more rock could have been produced, the domestic market would have absorbed it. It is confidently expected that returns for the present year will show a considerable increase and that the industry will soon resume its former proportions. A noteworthy fact is that the restricted exports have sent much of the highest grade rock to the domestic manufacturers and these latter will probably insist on using it in the future.

Like Florida, the Tennessee field has had its labor difficulties, and claims to have suffered particularly from inadequate transportation facilities. Its production in 1919 was about 460,000 tons and it is expected to show an increase for the present year.

The Charleston field, which appeared about to be abandoned because of mounting costs of operation and low grade of rock recovered, showed an increased production in 1919. About 100,000 tons of 60 per cent b.p.l. rock was marketed. Because of continued shortage in the Florida supplies it is expected that Charleston may do as well the current year.

DEVELOPMENTS IN THE WESTERN FIELD

The important developments have been in the Western field. The Anaconda Copper Co. is now producing double superphosphate, making sulphuric acid from smelter fume in a Larison packed cell plant, and obtaining the rock from the company operating at Paris, Idaho. The Anaconda company has added to its phosphate rock holdings at Melrose and Garrison, Mont., a large deposit in Soda Springs Canyon, Idaho, and is assembling a large mine and milling equipment, and a railroad is being built from the main line of the Oregon Short Line at Soda Springs to its proposed workings.

The Western Phosphate Co.'s mine, about three miles from Paris, Idaho, is connected by rail with the Oregon Short Line main line at Montpelier. The rock taken from this mine is white or light gray in color and appears to be very uniform in composition, the dried rock analyzing better than 72 b.p.l. It is claimed that the vein from which this rock is taken is 6 ft. in width and it has been traced for nine miles on land owned or controlled by the company. The other rock in the Western field is brown or black in color, usually harder

than the Paris rock and lower in phosphorus content, although there are some very large veins much higher in phosphorus content.

The Western Phosphate Co.'s main tunnel has now been driven about 2,000 ft. on this vein. The company has established a camp with large mining facilities, has a mill for crushing and drying with a daily capacity of 350 tons, another under construction with a daily capacity of 400 tons and a fine grinding mill with a capacity of eighty tons daily. The company has been shipping continuously since April of the current year to the Middle Western States, to the Pacific Coast and to the Orient. For the latter trade large loading bins have been constructed at Portland, which has handled the bulk of the export trade. The Western Phosphate Co. is associated with the interests controlling the large high-grade deposits near Border, Wyo., and in the Crawford Mountains, Utah, the largest reserves of high-grade rock in the world. The American Phosphate Co. is working a deposit about five miles from Montpelier and is reported to be producing about sixty tons a day with an augmented production promised at an early date, and there are several other shippers of small tonnages in the area. The total shipped from this area in 1919 was about 16,000 tons. The current year will probably see this figure quadrupled, the bulk of the material being taken from the mine at Paris, and as the black rock is rapidly winning friends as its merits become known to the trade, a steadily increasing production from this field can be expected. The long delayed but apparently now assured future of this industry will be a potent factor in developing the early manufacture and greatly increased use of mixed fertilizers in the Western States.

EXPORTS OF PHOSPHATE ROCK

The export of phosphate rock, which approximated 1,500,000 tons in 1913, gradually fell to less than a tenth of this during the war, but commenced to pick up as vessels for its transport became available, being 143,455 tons in 1918, about 380,000 tons in 1919, and will undoubtedly show a substantial increase for the current year. The bulk of the exports are from Florida, and go at present mainly to northern European ports. Japan has become a large buyer, and promises to increase its demands, especially upon the Western field.

The continued high price of sulphuric acid has served to direct more attention during the past year to other possible means of producing phosphoric acid. Volatilization of the pentoxide from the electric furnace, it is now pretty generally accepted, is technically simple and efficient, but not commercially practicable without much cheaper power than is now available. Waggonman's experiments at the Washington laboratory of the Bureau of Soils, in volatilizing from a furnace similar to an ordinary iron blast furnace, appear to promise that a commercially economical process can be developed. While the process has been devised with the waste phosphatic materials of Florida in mind as the raw material, it would seem to lend itself particularly well to the phosphates of the Western field and the conditions there encountered.

There has been a very considerable interest in more concentrated forms than the ordinary superphosphate containing 16 to 18 per cent soluble phosphoric acid. Several organizations are now marketing "double" supers containing as much as 50 per cent soluble phos-

phoric acid (P_2O_5) and approximating pretty nearly the composition of pure monocalcium phosphate. Some confusion has arisen because certain interested parties have described these more highly concentrated phosphates as "treble" superphosphates because they contain three times as much "available" phosphoric acid (P_2O_5) as do ordinary superphosphates.

AMMONIUM PHOSPHATES

There is a growing interest in ammonium phosphates. The American Cyanamid Co.'s several grades of "amophos" have proved that such compounds are very valuable from technical considerations, but the relative scarcity and high price of ammonia since the armistice has checked the developments in this direction. It would appear to be far more advantageous to market ammonia as phosphate rather than as a sulphate. Naturally, the coke-oven installations, which are the principal producers of ammonium sulphate, hesitate to make the change, largely because they fear that it would involve a more or less complete scrapping of their present equipment. The writer's own experiments have convinced him, however, that only very slight modifications would be desirable and that it will be but a short time before much of the phosphoric acid used as a fertilizer will be supplied the trade in the form of ammonium phosphates.

THE POTASH SUPPLIES

Supplies of potash are yet far below the demand, and at the present writing there is a tendency toward higher prices, although there is a prospect of improvement in the quantity coming from abroad and produced from domestic sources. During 1919 about 112,000 tons of potash salts was imported, practically all of it in the second half of the year, and the importations for the present year will undoubtedly show a very considerable increase. But in the writer's opinion it will be some years yet before imports can be expected to reach pre-war figures, or before prices will be materially lowered. He does not expect that prices will approach pre-war levels for many years, if ever.

Neither France nor Germany has any interest in furnishing potash to the United States, other than the money return or its equivalent in commodities. They are likely to recognize no other inducement than a large money return. The money value of the total potash imports of the United States in 1913 was just about \$15,000,000. At present prices this importation would be worth just about \$50,000,000. But present prices would certainly not exist if such quantities were actually available. Probably \$30,000,000 would be a liberal estimate of the value of the importation to the United States, and it would cost more than half this figure to mine and land the salts in the United States. To one who has kept in touch with the actual operations in the French and German fields it seems quite unlikely that either could command much more than half the American market if the other chose to compete.

The total probable realizable return from the American market is not, therefore, particularly attractive to either the French or the German authorities, and under the internal conditions in both countries it is more desirable, from their viewpoints, to maintain high prices and furnish a much restricted tonnage. France desires above all things in an industrial way to become Europe's master producer of iron and iron products,

and she is woefully short of man labor. She does not, therefore, look with favor on permitting any miner to work in the potash mines of Alsace who can be employed in the iron mines of the Briey, Lorraine or the Saar, or the coal mines of Lens. At the same time she is not going to permit Germany to build up the potash export trade at her expense. On the other hand, Germany has troubles of her own. The potash mines are now largely in the control of the laborers themselves. Production is not particularly remunerative or attractive. Repairs and renewals have not been kept up. Transportation facilities are wretched. Labor appears more necessary to other industries and the other industries appear more attractive and remunerative. The old trained crews are broken up.

On the whole, it seems probable that for years to come both countries will produce their own requirements and small surpluses for export, but that America's hopes of obtaining any large part of this surplus is only by paying what appears to us as exorbitant prices. Consequently, we shall have to develop our own resources or remain content to use much less potash than appears to be the plain requirements of the country.

DOMESTIC PRODUCTION OF POTASH

In 1919 our domestic production was approximately 120,000 tons of salts containing 32,418 tons of actual potash (K_2O), this being less than 60 per cent of the production of 1918. The falling off was due mainly to

the apprehension of a great influx of foreign potash at cheap prices. Many enterprises were completely abandoned; but, as the expected flood of foreign salts failed to materialize, the stronger and better organized enterprises resumed operations and the current year will probably show a production equivalent to more than 100,000 tons of actual potash (K_2O). If the writer's judgment continues to be confirmed by the size and cost of the foreign imports through the coming fall season, it is reasonable to predict a greatly increased development of domestic resources during the coming year, and it would not be surprising to see the 1921 production approach an equivalent of 250,000 tons of actual potash, the pre-war annual requirements of the country. It is certainly true that the interest in American "potash" is much more keen today among the larger fertilizer manufacturers and that the prejudice that formerly existed against it, largely because some of the Western salts contained appreciable quantities of borax, is fast disappearing, since the producers have learned how to avoid this objectionable constituent.

POTASH SALTS FROM SALINES

The principal interest in the domestic production during the current year has been in the recovery of potash salts from salines. In Nebraska some of the ponds which had been pumped out and apparently exhausted in 1919 filled again with the snow and rains of the following winter and were found to contain again

workable quantities of potash salts to an extent little or no less than formerly. All theories that this field will be exhausted within a few years have been abandoned, and there is greater activity there than ever before. The practice in the larger plants has become standardized. The brine from the outlying ponds or lakes is pumped to a near-by "plant pond" through wooden pipe lines and discharged in such a way that there is a current produced in the pond, the surface is kept in motion and there is more or less spontaneous evaporation. Evaporation by sprays and towers is not attempted, as the consensus seems to be that drift losses would be too great. The brine is taken from the bottom of the plant pond, through ordinary sand points with ordinary iron centrifugal pumps, to multiple effect evaporators and is concentrated to a solution of about 31 deg. Bé. hot, when it flows or is forced into a revolving iron tube, countercurrent to an oil flame and desiccation completed. Dust losses appear to be small and recovery of them efficient. A serious trouble is the sticking of the drying salts to the shell of the rotating tube. Rails are sometimes inserted to break the salts loose. Common practice is to have a workman walk back and forth on a platform and strike the rotating tube or kiln with a sledge. The desiccated salts are shipped as they come from the drier. They consist of a mixture of the sulphates, carbonates and chlorides of potassium and sodium with more or less organic and siliceous matter. Sulphate of potash is the predominating component, the potash content running generally from 27 to 30 per cent, sometimes higher. The operations are, it must be admitted, quite crude and readily susceptible of improvement. What has been accomplished elsewhere with American brines makes it reasonably certain that a phase rule study of the brines would soon and easily lead to modifications of the process that would produce a high-grade potassium sulphate and a merchantable sodium carbonate, with an increased value to the plant output.

OPERATIONS AT SALDURO, UTAH

At Salduro, Utah, the brine is gathered in an extensive series of ditches and conducted to shallow ponds, where it evaporates spontaneously, depositing a crystalline mass of potassium and sodium chlorides and leaving a concentrated mother liquor containing magnesium chloride with a very little of the chlorides of the other two bases. When the mother liquor has reached the desired concentration the deposited salts are harvested. A tractor pulls through the brine a buggy fitted with a scraping device which harrows the salts and draws them to the foot of an elevator. A second tractor draws, at the same time, a line of buggies into which the elevated salts are discharged, being washed and drained in the operation. The harvested salts are drawn to a stockpile at the near-by refinery. Accumulated mother liquors nearly saturated with magnesium chloride are stored in special ponds. The refining of the potassium chloride is effected by treating the mixed chlorides with a hot saturated solution of sodium chloride, the resulting clear liquor being then run into crystallizers, which are shallow iron pans fitted with brine pipes so that cooling can be hastened by artificial refrigeration. The surface of the brine pipes is kept clear by mechanical scrapers, which also gather the precipitated potassium chloride. A product of practically any desired commercial degree of purity can

thus be prepared. The reputed operating costs per unit of potash produced are low as compared with other enterprises in this country.

DEVELOPMENTS AT SEARLES LAKE, CAL.

At Searles Lake, San Bernardino County, Cal., there are three operating plants and another is in early stages of construction. One of the operating plants is following a solar evaporation scheme, and treating the resulting salt mixture. It is offering salts to the market, hence one may infer that it has developed a successful technique. The principal producer is the plant of the American Trona Corporation, which appears to have passed successfully a long and expensive pioneering campaign and emerged with a good economical process founded upon a careful, comprehensive, scientific investigation of the possible equilibria conditions in the brine which impregnates the twelve square miles of salt body in the lake. Although the level of this brine varies from a depth of a few inches above the level of the salt body in winter to a few inches below in summer, the brine does not vary in composition appreciably, if drawn from near the bottom of the salt body, the latter reaching a depth of 100 ft. or more in places. The brine contains chlorides, sulphates, carbonates and borates of potassium and sodium, being presumably saturated with respect to these salts and such combinations of them as can exist at the temperature of the bottom of the lake or salt body. On evaporation, which is carried out countercurrent to the stream flow in a multiple effect, sodium chloride, with other salts, is precipitated. The resulting hot mother liquor is then cooled quickly and quietly by artificial refrigeration, when potassium chloride is precipitated as a crystal meal. This meal is then washed and dried in a centrifuge, yielding a salt of 90 to 95 per cent purity and containing not more than a trace or inconsequential amount of borax. The mother liquor from the potassium chloride crystallization is then agitated, when a crystal mass is precipitated, which, when dissolved in a minimum amount of water, filtered and cooled, deposits a crop of very high-grade borax crystals. This last crop is augmented by passing air containing carbon dioxide through the liquor. It is possible that high-grade carbonates of soda will be added to the regular output of the plant. At present the grade of potassium chloride produced by this plant is so high that the entire output is absorbed in the alkali industry. Its output will shortly be tripled following plant readjustments now in progress, and it will then probably be an important factor in the fertilizer industry.

OPERATIONS ELSEWHERE

The production of potassium sulphate of a very high grade by the plant of the Armour Fertilizer Works at Marysvale, Utah, where the mineral alunite is roasted and leached, is now reported to be about fifty tons daily following enlargements and improvements of plant equipment. There is a renewed activity in alunite projects the past few months, but no other development worth recording.

Aside from cement mill operations, there is little to note in the production of potash salts from silicate rocks. The great hopes of last year that this one would see a large production of soluble potash salts from leucite have not materialized. The process tried out on a large scale at Green River, Wyo., was found to

be unsuited to plant operations as planned, although a number of carloads of a high-grade muriate were produced and shipped before an accumulating deficit in their financial resources forced its backers to suspend further efforts to modify it to meet equipment limitations. New methods for utilizing this source of potash are known to be under investigation by at least two large commercial organizations. Kelp as a source of potash is of vanishing importance at present, but not necessarily permanently. Other domestic sources of potash are not at present of sufficient relative importance to call for special notice or comment.

THE NITROGEN SUPPLY

The nitrogen supply will, in the main, continue to be cottonseed meal for some time to come, but it seems to be inevitable that this material will more and more be consumed as an animal food as feeders learn better ways of so using it. The same thing will be true of blood, tankage and fish scrap. Base goods or that indefinite conglomeration produced by treating organic waste such as leather scrap, feathers, etc., with sulphuric acid, will, however, continue to be used to greater and greater extent. Such ingredients are now frequently incorporated directly with superphosphate as the rock is mixed with the acid. There are prospects of an increased production of ammonia from byproduct coke ovens and it seems reasonably certain that there will be a much increased importation of nitrates from South America. But the greatest interest is and will continue to be in the artificial production of fixed nitrogen from the illimitable stores in the atmosphere. It may be frankly admitted that the high hopes developed during the war have not been realized by a wide margin. It would be foolish to assume that they will not be so realized sooner or later, and it seems only reasonable to expect that means will be found to continue the investigations of the last few years until it can be determined which of the various processes can properly survive under ordinary peace conditions in the United States.

To discuss satisfactorily the recent work on the various processes for fixing atmospheric nitrogen and the apparent merits or demerits would require a separate article and will not be attempted here. So far as the immediate interest of the fertilizer trade is concerned, two instances are apparently of dominating importance. A way must be found to proceed with actual production at Muscle Shoals, Ala., which will not involve unjust or injurious competition between the Government and established private enterprises. It should not be difficult for reasonable men to devise a plan which would ultimately redound to the interests of all concerned.

WORK ON MANUFACTURE OF AMMONIUM CHLORIDE

Perhaps the most striking announcement of the year is that the General Chemical and the Solvay companies have united to build a large plant for the production of ammonia by the Haber process, a desirable and economical adjustment of products of the Solvay and Haber processes having been worked out. As a result a very large tonnage of ammonium chloride will soon be on the market, which will readily be absorbed, it is expected, by the fertilizer manufacturers. A similar development is going on in England, where the Mond and Solvay interests are united for the purpose. It is reported that in France, where the scheme of adjust-

ing the two processes to each other's needs was first worked out, the problem of disposing of the large production of ammonium chloride as a fertilizer was carefully studied with pot and plot tests, with quite satisfactory results.

POSSIBILITIES FOR USE OF AMMONIUM CHLORIDE

Possibly there are some crops with which it would be inadvisable to use ammonium chloride. Tobacco is a case where one would be suspicious until actual tests are made. But for crops in general there seems to be no reasonable doubt that ammonium chloride would serve as well as any other salt as a carrier of nitrogen. An advantage is claimed for ammonium chloride, that it is the most concentrated form of ammoniacal nitrogen that can possibly be made commercially available. Of course ammonium nitrate contains an even higher percentage of nitrogen, all available for plant nutrition, but there is no prospect of this salt coming into use extensively in this country until there is much cheaper power than is now available, or ocean freights from Norway far lower than now seems probable. Whether the new salt will delay the development of plans to put ammonium phosphates on the domestic market is also an interesting question which can not be answered immediately.

SUMMARY

The most important developments of the current year, for the fertilizer industries, are:

The very great gain in public confidence.

An increased use of fertilizers in the Western States.

The opening of the Western phosphate deposits.

The revival of domestic production of potash.

The preparation for an early production of fixed nitrogen on a large scale as a byproduct of the soda industry.

The resumption of an export business.

The trials and tribulations of a reconstruction period have been met satisfactorily, on the whole, and the industries will be the stronger in the future for the lessons forced upon them.

Development of Egg-Products Industry in China

Perhaps no single industry has developed more rapidly in China than has the production of egg products during the war period. The eggs were collected in small factories formerly, but now these have become larger and are situated in the commercial centers, to which places the raw egg is brought in very large quantities. In 1913 there were exported from all of China 20,796,400 lb. of albumen and yolk and 30,266,845 dozen eggs, while in 1919 there were exported 80,824,267 lb. of albumen and yolk, 28,843,416 dozen eggs and 25,094,133 lb. of frozen eggs. These exports were valued at \$4,350,290 in 1913 and \$33,883,259 in 1919.

Many factories with the most modern equipment have been located in the various parts of China, Shanghai being the most important point, and Nanking, Hankow, Suchow and other places having manufacturing plants of considerable consequence. The exportation of frozen eggs is going forward in increasing quantities, and this article reaches the American as well as the European market. It cannot be shipped to the American market in the quantities that the desiccated egg can be, as it requires refrigerating vessels, which are not frequently run on the Pacific.

Notes on Nickel

Brief Notes on the Metallurgy of Nickel, and Data on the Uses and Applications of Various Grades—Information on the Limitations in Rolling, Annealing, Welding and Electrodeposition

BY PAUL D. MERICA*

FOR the past two years the author has been interested in the collection of accurate information and data concerning nickel and its alloys and in view of the increasing importance of this metal both in the pure form and as an alloying element in the composition of many interesting alloys has deemed it of sufficient value to present some of this material in a series of articles. Although certain phases of this subject have previously been presented in a very satisfactory manner,¹ much information which should be very useful is still in such scattered form as to be rather unavailable. It has been the attempt to pay particular attention to those chapters of which this was true as well as to include a great deal of data particularly on nickel and its alloys other than nickel steel which has hitherto been unpublished.

Much assistance has been had in the collection of this material, for which the author wishes to make grateful acknowledgment: to A. J. Wadhams and J. F. Thompson of the International Nickel Co., to W. H. Bassett of the American Brass Co., to W. B. Price of the Scovill Manufacturing Co., to W. Blum of the Bureau of Standards, and to the Driver-Harris Co., the Electrical Alloys Co. and the Hoskins Manufacturing Co.

SOURCES

The ores from which commercial nickel is obtained are of three classes: (1) *Sulphides*, represented by the pyrrhotite-chalcopryite ores of Sudbury, Canada, and of Norway, and which contain from 1 to 3 per cent each of copper and nickel, with the mineral pentlandite as the nickel carrier. (2) *Silicates and oxidized ores*, which are found principally in New Caledonia and contain from 5 to 6 per cent of nickel (plus cobalt), with garnierite as the principal nickel carrier. (3) *Arsenical ores*, which are found in Canada and on the Continent, in Saxony, and elsewhere. Of these, the first two classes only are of much commercial importance, and the first class furnishes by far the greater proportion of the present output of this metal. In addition to the metal produced from these ores, a small amount of nickel is recovered annually from blister copper.

SMELTING

Sulphide ores are first roasted and then smelted in blast furnaces to a matte containing approximately 24 per cent of nickel plus copper, 45 per cent of iron,

and the remainder sulphur. This matte is then blown in a converter to a mixture essentially of nickel and copper sulphides, which is ready for the refining.

Although the smelting practice of the companies operating with sulphide ore of the Sudbury type is essentially the same, as well as the product (which is usually known as bessemer matte), the refining of this matte to metal and the separation of the nickel and copper are accomplished by quite widely different processes, of which the following three are the most important:

REFINING

(1) The Hybinette process, which is in operation in Norway, is essentially an electrolytic one. The matte is roasted to remove the bulk of the sulphur and leached with 10 per cent sulphuric acid, whereby a large proportion of the copper with very little nickel is dissolved out. The residue is melted and cast into anodes, containing about 65 per cent nickel and from 3 to 8 per cent sulphur. These anodes are then treated by electrolysis, with cementation of the contained copper by anode scrap. In this manner nickel cathodes and both cement and cathode copper are obtained.

(2) In the Mond process (which is operated in England) the bessemer matte is first roasted and the copper removed in part by leaching with sulphuric acid with the formation of a solution of copper sulphate. The residue, containing nickel oxide with some copper oxide and iron, is reduced at a low heat to a finely divided metallic powder. This is carefully protected from contact with the air, and carbon monoxide is passed over it at from 50 to 80 deg. C. At these temperatures nickel-carbonyl vapor is formed, later to be decomposed by passing it through a tower containing shot nickel heated to about 200 deg. C. A layer of nickel is formed on the shot and the carbon monoxide is regenerated and returned to the volatilizing towers. The nickel shot is alternately exposed to and withdrawn from the action of this gas and in this way a series of concentric layers of nickel are built up around the original nucleus, like the coats of an onion, a means of ready distinguishment.

(3) The Orford process, which is the oldest process for the separation of copper and nickel, is being operated in this country. The bessemer matte is melted with salt cake, or niter cake, together with coke in the blast furnace. The sodium sulphide formed by the reduction of the sodium sulphate by the coke together with the copper sulphide forms a matte of low specific gravity. The product of the blast furnace is allowed to cool in pots, in which a separation occurs, the upper portion or "tops" containing the greater part of the copper sulphide together with the sodium sulphide, the lower portion or "bottoms" containing the greater part

*Superintendent of Research, International Nickel Co.

¹"Physical Properties of Nickel," by D. H. Browne and J. F. Thompson, *Bulletin*, A.I.M.E., August, 1919. Report and Appendix of the Royal Ontario Nickel Commission, A. T. Wilgress, Toronto, 1917. "Manufacture and Uses of Alloy Steels," by H. D. Hibbard; John Wiley & Sons, N. Y., 1920. "Die Spezialstähle," by G. Mars; Ferdinand Enke, Stuttgart, 1912. "Steel and Its Heat Treatment," by D. K. Bullens; John Wiley & Sons, N. Y., 1918.

of the nickel sulphide. The "tops" and "bottoms" are readily split apart when cold. Several treatments are required to effect a sufficiently complete separation. The "tops" go to the copper cupola and converter, where they are blown to blister copper. The "bottoms," consisting essentially of nickel sulphide or matte, are roasted and leached alternately until they have been completely changed to nickel oxide. This is reduced with charcoal in crucibles or reverberatory furnaces to metallic nickel at a temperature above its melting point such that the resulting product may be cast into ingots or blocks or poured into water to form shot. Electrolytic nickel is also produced by casting this reduced metal at once into anodes, and obtaining pure nickel cathodes from them by electrolysis with an electrolyte of nickel sulphate.

The silicate ores of New Caledonia, which contain no sulphur, are first mixed with sulphur-bearing materials such as gypsum or pyrites and smelted in the blast furnace to a matte, which is shipped for refining, which in this case, in the absence of copper, consists merely of roasting the nickel matte to oxide and reducing the oxide with charcoal.

COMMERCIAL GRADES

Nickel appears on the market in the following forms:

(a) Grains, cubes, rondelles or powder reduced at a low temperature from nickel oxide and not fused in the process of manufacture.

(b) Nickel deposited in concentric layers from nickel carbonyl and not fused in the process of manufacture.

(c) Nickel deposited electrolytically in the form of cathode sheets.

(d) Nickel in the form of blocks or shot made by reducing nickel oxide above the melting point of nickel and casting the resulting molten metal or pouring it into water.

(e) Malleable nickel made in the same manner as (d) but treated with some deoxidizer before pouring into ingots. This nickel appears in the usual commercial forms—i.e., rods, sheet, wire, etc.

Most of the commercial production of nickel falls in class (d).

The International Nickel Co. has described the grades of material which it produces and contributes the average analyses of these materials found in Table I.

"A" shot nickel is a high-carbon nickel used by manufacturers of anodes for nickel plating.

"X" shot nickel is a purer material used by the manufacturers of crucible nickel steel and of nickel silver.

Ingot or block nickel is almost identical in composition with "X" shot. It is sold in 25- and 50-lb. blocks or ingots and is used in the manufacture of open-hearth and electric steel.

Electrolytic nickel in the form of cathodes 24 x 36 in., weighing about 100 lb., or in smaller squares, is used in the manufacture of high-grade nickel silver and cupro-nickel alloys.

Malleable nickel intended for rolling into sheets or rods or for drawing into wire is made in various grades according to the purpose for which it is destined. All malleable nickel is treated before casting into ingots with some deoxidizer, generally magnesium, for the purpose of removing the nickel oxide present and making the metal suitable for rolling or forging. Manganese is also added both for the purpose of cleaning the metal and as an alloying element. Nickel cannot in general be rolled or forged without this preliminary treatment with a deoxidizer.

Grades A and C malleable nickel ingots are produced by the International Nickel Co. for rolling into rods and sheets and drawing into wire.

Grade D malleable nickel is high-manganese nickel having practically the same analysis as grade C

NOTE.—The nickel values of some of the samples mentioned by the Royal Ontario Nickel Commission include nickel only, while in other cases they include nickel plus cobalt. International Nickel Co. metal contains about 0.4 per cent cobalt, which is usually included in the copper analysis.

(Table I) except manganese varies from 2 to 5 per cent. This is used principally for spark plug wire to resist the action of high temperatures and combustion gases.

Table I gives the results of a number of chemical analyses of samples of commercial nickel, including that of foreign manufacture.

Besides the commercial forms of nickel described above, the metal is on the market in the form of anodes for the metal-plating industry. These cast anodes are quite variable in composition and contain from 88 to 95 per cent nickel together with iron, aluminum, tin, silicon, sulphur, and carbon. A typical analysis of a commercial anode is the following:

Graphitic carbon	1.70	Copper	0.15
Silicon	0.50	Aluminum	0.03
Iron	0.80	Nickel	96.82

USES OF NICKEL

The principal commercial application of nickel is in the manufacture of nickel steel, and this industry absorbed fully 75 per cent of the total nickel production during the war and probably 65 per cent normally. Nickel steels will be discussed briefly later.

Besides its use in steel nickel is used quite extensively as an alloying element with non-ferrous metals, principally copper; many of these alloys will be discussed in more detail. About 15 per cent of the production is utilized in the manufacture of alloys of nickel, such as cupro-nickel and especially nickel silver, the former series of alloys having come into prominence during the war. Nickel coinage and the electroplating industries may each absorb from 3 to 5 per cent of the production, the latter requiring the metal both in the metallic form and in the form of nickel salts; the single salts $\text{NiSO}_4 \cdot 7\text{H}_2\text{O}$ and the double salt $\text{NiSO}_4 \cdot (\text{NH}_4)_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$.

The production of malleable nickel, although never relatively large, has amounted to about 5 per cent of the total production and is steadily growing in volume as the properties of the metal in this form because better known. Malleable nickel is produced in all commercial forms and is used principally for coinage, cooking utensils (chiefly abroad in Germany and Austria) and other ornamental and household stampings and fittings. In the form of wire it is much used for motor ignition spark plug points, for the suspension wires in electric light bulbs, for electrical resistance pyrometers, electrical instruments, and recently in the construction of the audion amplifier.

Some malleable nickel is produced in the form of castings for apparatus such as digesters and evaporators for the chemical industry, for which its resistance to corrosion in sulphuric and other acids make it peculiarly suitable.

The Edison storage cell contains nickel both in the form of nickel oxide and as nickel anodes. Finely divided nickel is much used as a catalytic agent in the hydrogenation or hardening of oils, following the discovery of this property by Sabatier and Senderens. Nickel oxide is used in the ceramic industries for the production of under- or holding-coats of enamel on steel and also for coloring glazes on pottery.

Nickel castings have been used with much success as rabble shoes by the International Nickel Co., in calcining furnaces roasting nickel matte. The shoes are exposed to oxidizing and to sulphurizing gases at temperature from 600 to 1,000 deg. C. and to severe mechan-

ical abrasion; they have stood up in this severe service for nine months, whereas iron shoes would last no more than from six to eight weeks.

CASTING PRACTICE

Nickel is cast from the furnace into open molds to produce blocks for remelting, into ingot molds after deoxidation with manganese and magnesium for the production of malleable nickel and into sand molds for nickel castings. It is also poured directly into water to form nickel shot.

For the production of castings, the metal in the form of blocks or shot may be remelted in crucibles or in an oil-fired or electric furnace with the addition of charcoal to reduce the oxide which is present and which is formed during remelting. When at the proper temperature, it is poured into a ladle and deoxidized in the same manner as for the production of malleable ingots and poured into molds. The chief difficulty in the remelting of nickel is in the proper adjustment of carbon and oxide content of the molten metal prior to deoxidation, and which is known as bringing the metal to pitch.

Platers' anodes are melted with carbon and may be poured at a much lower temperature than malleable nickel and do not require deoxidation of any kind; they are consequently much easier to handle in the foundry than low-carbon metal.

The molding of nickel castings follows the practice used for steel castings, generally speaking, an allowance of $\frac{1}{4}$ in. to the foot being made for shrinkage.

Other than the process of deoxidation, which is absolutely essential, the production of malleable nickel ingots requires no novel operations not known, for instance, in the steel industry. Deoxidized nickel solidifies without blowholes but with a pronounced pipe, which renders necessary the use of proper risers or hot-tops and properly designed molds.

ROLLING, FORGING, ANNEALING

In the hot-working of nickel, both the temperature and the condition of the heating flame should be subject to careful control. The temperature for preheating and rolling should be from 1,100 to 1,180 deg. C. Ingots should not be subjected to temperatures much in excess of this, as they then become somewhat hot-short. Below this temperature the metal may be too hard to roll satisfactorily. The flame used for heating should be as nearly neutral as possible and a low-sulphur fuel (oil) is essential for successful heating.

For hot-rolling bars and rods of the usual cross-sections, the same designs of rolls as are used for steel may be and are employed with success. Pure nickel and nickel alloys of high nickel content are very easily guide-marked when hot.

The remarks of the first paragraph above apply also to the forging of nickel. Nickel is much more successfully forged under the hammer than under a press; in fact, the metal has a pronounced tendency to crack under the slow action of the press, which may be due to the fact that the surface cools more readily than under the quick blows and short contact of the hammer.

In order to soften nickel which has been worked cold it must be heated to at least 750 deg. C., the minimum temperature of the annealing range, and allowed to remain in the furnace until thoroughly heated throughout. It may be cooled rapidly or slowly, as desired, as there is no alteration in the properties of the metal

produced by cooling after annealing. For the commercial annealing of nickel a temperature of 900 deg. C. should be used, as this will insure a more thorough and homogeneous anneal.

Price and Davidson² have studied the annealing of nickel of commercial pure grade (A) and their results are shown in the accompanying figure. The annealing range for the metal is from 600 to 800 deg. C.; commercially the metal is usually annealed at 900 deg. C.

Whenever possible the metal should be annealed in tight boxes to prevent the formation of oxide, and any oxide formed may be reduced by the creation of a reducing atmosphere in the box, either by the presence of a small amount of charcoal or by the admission of some reducing gas. When annealing is done in this manner no pickling is required and on account of the difficulty and expense pickling should be adopted only as a last resort.

If necessary, pickling may be accomplished by the use of sulphuric acid with some oxidizing agent, such as ferric sulphate or chromic acid, at a temperature around 60 to 70 deg. C., but it is a slow and tedious process.

WELDING AND SOLDERING

Nickel cannot be smith-welded owing to the formation of a coating of nickel oxide which cannot be fluxed and which prevents the adherence of the two surfaces to be welded. On the other hand, under a reducing atmosphere the metal may be welded, such as by the use of the oxy-acetylene torch, or by electric-resistance welding. It is by the latter process that nickel wire is welded to iron wire to form tips or points for spark plugs.

Under suitable reducing conditions nickel may be plastically welded to steel, and an interesting process, invented by Dr. Fleitman about thirty-five years ago, of producing nickel-coated steel sheets is based upon this possibility. A steel sheet bar, about $\frac{3}{4}$ in. thick, is cleaned and pickled and placed between two thinner plates of clean nickel. Around the whole is wrapped a thin steel sheet, which protects the nickel against oxidation and is dissolved off by later pickling. The compound sheet bar is heated in a reducing atmosphere and then rolled and crossrolled into a solid, compound sheet. Needless to say, the nickel coating so produced is thicker and more durable than electrolytically deposited metal.

ELECTRODEPOSITION

Outside of the production of electrolytic nickel, the chief chemical application of nickel deposition is in the nickel plating of steel, brass, zinc and numerous alloys, generally in the form of castings or stampings, partly

for protection against corrosion but primarily for the improvement of appearance. Its chief value for this purpose lies in its relative hardness and its resistance to abrasion and atmospheric corrosion. Nickel is used to a limited extent in electrotyping, in which case it may be deposited directly upon the wax or lead mold, producing a true nickel electrotype; or it may be deposited upon the face of a finished copper plate, making a nickel plated electrotype. In general, the function of the nickel upon electrotypes is to give a harder wearing surface; which is also more resistant than copper to the action of the colored inks frequently employed. The production of nickel articles such as tubes by deposition upon wax or other fusible molds has never been commercially successful, though processes recently devised for this purpose appear promising.

PRINCIPAL SALTS OF NICKEL USED IN PLATING AND ELECTROTYPING

The principal salts of nickel used in plating and electrotyping are nickel sulphate and nickel ammonium sulphate (known commercially as "single" and "double" salts respectively). The nickel-ammonium sulphate has the advantage of better conductivity but the disadvantage of lower solubility. Mixtures of the two are frequently used. In 1878 Weston patented the use of boric acid in nickel baths, which has come into quite general use. Boric acid appears to favor more uniform

operation of the baths, and to produce brighter deposits. Experiments of L. D. Hammond³ indicates that the essential function of boric acid is the maintenance of a uniformly small hydrogen-ion concentration in the solution. He found that good deposits can be obtained from solutions slightly acidified with strong or weak acids, none of which, however, is so suitable as boric acid for continued service.

Pure nickel exhibits in a marked degree the phenomenon of passivity when it is made the anode in most acids or salts. In consequence the use of pure nickel anodes

²Discussion of paper by Browne & Thompson, *Transactions, A.I.M.E.*, 1919.

³"Electrodeposition of Nickel," *Trans., Am. Electrochem. Soc.*, vol. 30, p. 201 (1914).

in nickel sulphate solutions would soon bring about an impoverishment in nickel and the liberation of free sulphuric acid. It has hence been customary to add to nickel anodes appreciable amounts of iron, carbon and tin, which by local action increase the solution tension of the nickel. Incidentally they lower the fusing point, and thereby facilitate the casting of the nickel anodes, and contaminate the solution with an accumulation of slimes. This may be prevented to a large extent by the addition of chlorides, or more recently of fluorides, to nickel baths, both of which reduce anode passivity and increase the corrosion of purer metal. Chlorides of sodium, ammonium, nickel or magnesium are frequently added. The fluorine is usually added in the form of hydrofluoric acid, though it is preferable first to neutralize this acid with nickel carbonate, thus forming nickel fluoride.

In addition to aiding in anode corrosion, the presence of sodium or ammonium chloride increases the conductivity of the solutions. Other salts are sometimes added to nickel solutions to increase the conductivity—e.g., ammonium sulphate (in the form of or in addition to nickel ammonium sulphate) and magnesium sulphate. Salts of organic acids, such as tartrates, citrates, etc., which have also been added, may serve, (1) to regulate the acidity, (2) to dissolve basic compounds, especially of iron, and (3) to reduce the rate of chemical deposition of nickel by more positive metals. The latter function is especially useful in the nickel plating of zinc and zinc alloys.

In general, nickel plating has been conducted at low temperatures, but Watts⁴ has shown that in solutions containing nickel chloride and sulphate, and boric acid, hot solutions may be employed to advantage, and may permit the use of much higher current densities.

FORMULAS OF VARIOUS TYPES OF NICKEL BATHS IN COMMERCIAL USE

The following formulas illustrate the various types of nickel baths in actual commercial use. It is not implied, however, that these formulas will always be satisfactory, much less that they are the best for a given class of work.

	Grams per Liter	Ounces per Gallon
<i>Nickel Electrotyping</i>		
Nickel ammonium sulphate...	45	6
Nickel sulphate	15	2
Sodium chloride	7.5	1
<i>Nickel Plating—Double Salt Solution</i>		
Nickel ammonium sulphate...	90	12
Ammonium chloride	22.5	3
Boric acid	15	2
<i>Nickel Plating—Single Salt Solution</i>		
Nickel sulphate	120	16
Ammonium chloride	22.5	3
Boric acid	15	2
<i>Nickel Plating (Watts)⁴—For High Current Density, or in Hot Solutions</i>		
Nickel sulphate	240	32
Nickel chloride	15	2
Boric acid	30	4
<i>Nickel Plating on Zinc (Hammond)⁵</i>		
Nickel sulphate	240	32
Nickel chloride	15	2
Boric acid	30	4
Sodium citrate	175	23

The Chemical Industry of Switzerland

BY DR. A. LANDOLL*

SWITZERLAND is exceedingly poor in raw materials and has to import practically everything (with but few exceptions) from abroad.

Switzerland's wealth of water power and the favorable position of the waterfalls made conditions somewhat easier for the chemical industry of the country after the problem of the transportation of electric power had been solved in the '80s and large power stations had been built on the Rhine, the Aar, the Doubs, the Rhone, etc. In particular a foundation was laid for electrochemistry and electrometallurgy which led to an enormous development, so that the condition of relatively cheap motor power could be fulfilled.

The second condition—namely, the existence of trained and skilled chemists, together with technical and commercial staffs—the chemical industry owes in the first instance to the high development of our federal and cantonal educational establishments, particularly the Federal University and Polytechnicum, and above all, the chemical institutions, which have always understood how to keep up an active and intimate contact between science and technics. All these factors have enabled the chemical industry of Switzerland to attain great prosperity in spite of the difficult circumstances in which it is placed.

The most important export branches of the Swiss chemical industry are the Basel aniline dye factories and the electrochemical and electrometallurgical works.

This comprises all the Swiss concerns which are occupied with the manufacture of artificial organic dyestuffs (aniline dyes) and the preparation of dyestuff extracts.

THE CHEMICAL-PHARMACEUTICAL INDUSTRY

Closely connected with the dyestuffs industry is the chemical-pharmaceutical industry, in which the Basel concern also participates. This branch made extraordinary progress during the war.

The chemical-pharmaceutical industry of Switzerland was established at a time when a number of chemical-pharmaceutical enterprises were already in existence abroad, especially in Germany. A great deal of courage and a keen spirit of enterprise were necessary in order to take up competition with the foreign industry, the reputation of which was already established. The plan thus tenaciously grasped and carried out with far-seeing vision prospered exceedingly, and today we may look with pride and happiness on the rapid and successful development of our native chemical-pharmaceutical industry. The factories were soon in a position to venture on independent labor in certain domains of pharmaceutical chemistry, and the preparations they have turned out have acquired a good name all over the world.

The export figure for pharmaceutical articles and drugs, which was 17,687,385 fr. in 1913, went up to 26,533,000 in 1919.

TAR DYES

The production of tar dyes increased from year to year and the Basel firms were keen competitors on the international markets. Since 1911 the Society for Chemical Industry, Basel, has taken up the manufacture

*President of the Swiss Society for Chemical Industry.

of artificial indigo and thus become a competitor of Germany. In order to be able to keep their place on the world's markets during the transition period and to compete successfully with Germany in future, the three leading Basel factories, the Society for Chemical Industry, the Chemical Works, formerly Sandoz, and the firm of J. R. Geigy, Ltd., formed an amalgamation in 1918 similar to that of the German factories, which provides for a community of interests for a period of fifty years. About 90 per cent of the total production of these firms goes abroad.

Founded in 1864 and transformed into a limited liability company in 1885, the Society of Chemical Industry at Basel now has a capital of 20,000,000 fr. and gives employment to more than 2,700 hands and 530 commercial and technical employees. Hence it occupies a not unimportant rank in the chemical industry of this country both as regards the manufacture of dyes and the preparation of pharmaceutical and photographic products.

During the last few years (from 1913 to 1919) the exports of aniline dyes went up from 25 to 123.6 million fr. The export value of artificial indigo rose in the same time from 3.9 to 12.2 million fr.

SYNTHETIC PERFUMERY

The synthetic perfumery industry was introduced into Switzerland in 1895, at first only on a small scale. The industry made rapid progress, however, and flowered in a comparatively short time. The six important firms which make these articles turn out natural perfumes by synthetic methods. The main business is done in exportation. The exports of perfumes and soaps totalled 16.1 million fr. in 1919.

The extension of the use of water power in Switzerland during the last two decades has contributed enormously to the development of the electrochemical and electrometallurgical industries. The oldest and at present the largest is the Aluminium Industry Co., Ltd., Neuhausen, with works on the Rhine Waterfall and at Chippis (established in 1888), which was the first in the world to produce pure electrolytic aluminum according to its own process. Nearly all electrochemical manufactures produced abroad are turned out in Switzerland too. The old methods based on chemical processes have been replaced by the electrolytic process, such as the manufacture of metallic sodium, caustic soda and chlorine, chloride of calcium, together with a number of other inorganic and organic derivatives of chlorine. We may further mention the manufacture of oxygen, hydrogen, nitric acid, hydrocyanic acid, nitrate of urea and their derivatives, then the persulphates, perchlorates, calcium metal, silicon, ferrosilicon, ferrochrome, etc.

EXPORTS

Thanks to the enormous demands on the part of foreign countries during the war for electrochemical and electrometallurgical products, the exports of these articles from Switzerland increased considerably, as may be seen from the following table:

	1913	1914	1915	1916	1917	1918	1919
	In 1,000 Tons						
Calcium carbide..	32	36	55	58	59	76	37
Ferro-alloys.....	16	17	19	23	23	16	10
Raw aluminum...	7	7	9	11	11	10	5
	<u>55</u>	<u>60</u>	<u>83</u>	<u>92</u>	<u>93</u>	<u>102</u>	<u>52</u>

The exports of these three articles reached their maximum in 1918, but they went down to almost half in

1919 after the demands of the belligerent countries had ceased. At the present time there are about eighteen electrochemical works in Switzerland. The manufacture of varnishes and paints, mineral and pigment dyes, printing and lithographing colors, glue, etc., has also taken a remarkably strong development.—*Swiss Exporter*, Special Edition for North America, p. 25.

The Removal of Nitrates by Means of Alcohol

BY R. SCHNEIDEWIND

Many analytic procedures demand the absence of nitrates. For instance, most methods for the electrolytic determination of nickel require that all nitric acid be expelled; in the determination of zinc in brasses, copper must be removed either by metallic aluminum or by sodium thiosulphate. Nitrates in the first case seriously affect the completeness of the separation; in the second case they oxidize the sulphur, hinder the copper precipitation, and if precipitation is completed there is a large quantity of colloidal sulphur that is very inconvenient to work with. In the separation of Zn and Al by means of H_2S in acid solution, in some electrolytic methods for determining Co, Fe, Cd and in many other cases nitrates must not be present.

Common practice is to add 10 to 15 c.c. of concentrated sulphuric acid and boil down until white fumes of SO_3 are evolved. This method gives rise to various objections. Considerable time is required to concentrate a solution of, say, 200 to 250 c.c.; there is always danger of bumping and spattering when a quantity of salts crystallize out; and as in the case of nickel, for instance, under some conditions complex sulphates are formed which are soluble only with difficulty.

The writer has used ethyl alcohol to remove nitrates in routine work—none remaining to interfere with any succeeding operation which would be incomplete in the presence of nitric acid. To a solution containing 20 c.c. concentrated HNO_3 and about 150 c.c. H_2O , 15 c.c. concentrated H_2SO_4 is added and then heated. When nearly boiling, 5 c.c. ethyl alcohol is added, taking care not to pour in too rapidly so that the solution boils over. From time to time 3 to 5 c.c. C_2H_5OH is cautiously added until further addition no longer causes an evolution of NO , fumes. It is then boiled five minutes longer to expel the excess alcohol. This will not give a positive test for nitrate with the usual brown ring reagent and does not oxidize the S in H_2S . The writer has found copper only to be affected when treated in this manner, some being precipitated as a cuprous compound.

About twenty minutes is required for the whole operation, including the time for boiling off the excess alcohol, thus effecting a great saving of time over the concentrating to SO_3 fumes method and without the danger of loss through spattering.

Laboratory, Studebaker Corp.

Sulphur Refinery to Be Erected in Portland

The Stauffer Chemical Co. has purchased a site in Portland, Ore., upon which to erect a plant for refining sulphur. Because of the increased railroad freight rates, great quantities of sulphur are moving from the Gulf of Mexico to Portland by the all-water route. Three full cargoes of crude sulphur in bulk have already been discharged at Portland for the Texas Gulf and Union Sulphur companies, and two more steamers have been booked to move sulphur cargoes from Sabine and Galveston, Tex., to Portland.

Survey of the Physics and Chemistry of Colloids*

Physical and Chemical Properties of the Colloidal Phase—Formation by Condensation and Dispersion—Symmetrical Structure—Resistance to Displacement in Solution—Viscosity and Colloidality—Aggregation and Other Structural Changes

By THEODORE SVEDBERG

THE science of colloids is a science of the micro-structure of matter. In it is reflected the tendency of modern natural science to deal more and more intensely with the problem of structure in its full extent. In the great science of the structure of matter, the science of colloids forms the domain that lies above molecular dimensions and beneath microscopic dimensions. In this domain we have a great number of those systems which are the basis of our material culture and the basis of life as a whole. All living beings are built up of colloids—almost all our food, our articles of clothing, our building materials, are colloids. Or, to mention some special systems, protoplasm, proteins, glue, starch, all kinds of fibers, wood, brick, mortar, cement, certain kinds of glass, rubber, celluloid, etc. The importance of colloid science for many industrial questions is, therefore, beyond all doubt.

The science of colloids is a rather young one. The field of study which it concerns has for a long time been disregarded. In order to be able to treat with success all the questions presented to us by industry, there is still much to be carried out in the department of pure colloid science. In what follows, I will try to give a short review of the scientific results so far obtained and of the problems which, in my opinion, need especial attention.

The various branches of colloid science are connected to such an extent that it is very difficult to treat the different questions separately. We will try to fix our attention on two principal problems: (1) The formation of colloids, and (2) the changes of structure in colloid systems. Connected with both these is the problem of the properties of colloids and the changes in these properties during the processes mentioned under problem 2.

The formation of a colloid may be effected in two ways, different in principle—viz., by condensation and by dispersion, according as one tries to obtain a micro-structural system, a colloid, from a molecular structural or a macrostructural system.

FORMATION BY CONDENSATION

In the case of a condensation process, the degree of "graininess" or the degree of dispersion will become higher as the degree of supersaturation increases, which must, of course, always precede condensation. This is the case when fogs are formed by adiabatic expansion of gases—e.g., cloud-formation in the atmosphere—when metal colloids are prepared by condensation of the vapors of metals from the electric arc, or when a slightly soluble substance—e.g., barium sulphate—is precipitated by means of a reaction between ions. The condensation

always proceeds from certain heterogeneities in the medium's condensation centers or nuclei. As such nuclei, we may have particles of the substance which is to be formed by the condensation—e.g., precipitation of gold on small gold particles when preparing gold hydrosols or gold ruby glass—or gas ions—e.g., fog formations in cases at low degrees of supersaturation—or complex molecules—e.g., fog formations in gases at high degrees of supersaturation. The manner in which these nuclei are introduced into the system under condensation is of great importance for the degree of dispersion of the colloid resultant. If the nuclei are not introduced into the system all at once, but gradually in the course of the condensation process, the particles will be very unequal in size.

The biologically important colloids—e.g., the proteins—are evidently all formed by condensation, but no details of this process are known. The tendency toward condensation manifests itself in the fact that even the protein molecules are, from a purely chemical point of view, condensation products.

FORMATION BY DISPERSION

In case of a dispersion process, there is always work to be performed against the surface tension or the cohesion force. Accordingly, such a process is, in contradistinction to a condensation process, a forced and not a spontaneous one. We know very little as to the relation between degree of dispersion and experimental conditions. When emulsifying fats and hydrocarbons, the surface tension may be lowered by the addition of small quantities of alkalis or soaps. Grinding, in general, does not lead to a very high degree of subdivision; but it is possible to increase the latter by adding an indifferent solid diluent which can easily be dissolved and removed, leaving the disperse phase suspended in the solvent used. Thus, colloid sulphur has been prepared by grinding sulphur with urea and putting the substance in water. A combination of grinding and chemical effects on the material may also be used. It seems that, in many cases, a prevention of the aggregation of the particles by means of suitable additions ought to render possible the preparation of high disperse systems by pure grinding.

Bubbles and foam might be regarded as a kind of colloids formed by dispersion. On spontaneously breaking up they form new disperse systems in which the phase that was previously the continuous one becomes the non-continuous one, and *vice versa*. The system "soap foam—air," with the soap solution as the continuous and the air as the non-continuous phase, is transferred on account of surface reduction—i.e., condensation—into the system "soap solution drops—air," with the air as the continuous phase. Mercury foam

*Read before the Faraday Society and the Physical Society, London, Oct. 25, 1920.

in water (produced by means of pumping water through mercury) breaks up into a mercury hydrosol partly very fine-grained.

CHANGES IN STRUCTURE

A newly-formed colloid may, immediately after its formation, undergo changes of structure of a more or less profound nature. On the other hand, it is nearly always possible to prevent the occurrence of such changes and therefore we have a right to distinguish and investigate the primary structure as the direct result of the colloid-forming process. Colloids with primary structure may conveniently be called primary colloids.

We have at our disposal several methods for the closer study of the structure. Almost every property of a colloid depends on the structure, and therefore, conversely, from the study of the properties of colloids we may draw conclusions as to their structure.

The most important and most obvious means is the microscope and the ultramicroscope. With their aid it is often possible to settle whether the colloid under investigation is of a grainy structure—e.g., a colloid gold solution in water—a gold hydrosol, or of a foamy structure—e.g., high disperse soap foam—or of a fibrous structure—e.g., soap solutions of a certain concentration. The number and approximate size of the discontinuities—e.g., the particles—may also be determined in this way. One may, for instance, count in the ultramicroscope the number of particles observed in a certain volume of gold hydrosol, and by means of analysis determine the content of gold present in the sol. From these figures we get the mass and approximate size if, for instance, we make the assumption that they are spherical. On the other hand, the ultramicroscope gives little or no information about the form or structure of the particles.

SYMMETRY

A means of deciding whether the particles are symmetrical is to be found in the study of the behavior of the colloids in magnetic or electric fields. Non-symmetrical particles are oriented by such fields and thereby impart to the colloid a certain, though in general very slight, degree of double refraction, which may easily be measured with great accuracy. In this way we have been able to settle that the particles in common sulphur hydrosols, prepared by oxidation of hydrogen sulphide, are spherical; but sulphur hydrosols, prepared by grinding sulphur with urea, are dissymmetrical. The particles in gold hydrosols prepared by reduction are dissymmetrical to a high degree.

OPTICAL PROPERTIES

Two other optical properties, viz., the light absorption and its accompanying phenomena, the scattering and polarization of light—the Tyndall phenomenon—may also in certain cases be used for structure studies. Theory, as well as practice, proves that these phenomena are, for instance, dependent to a great extent on the degree of dispersion of the sol. The form and structure of the particles also influence the said properties, but in a manner hitherto unknown. The emission of light from illuminated particles especially—the Tyndall light cone—varies to a great extent with the size of the particles or the degree of dispersion. Colloid solutions that contain very small particles—e.g., Faraday's gold hydrosol—give only a slight emission; the light cone is scarcely visible. Those with large particles—e.g., gold

sols made from Faraday's gold sols by allowing the particles to grow in a reduction-mixture—emit very much light; the Tyndall cone is very prominent. The optical properties of the particles also play a great part. Thus metal particles emit much light, particles of silicic acid or of gelatine only a little.

RESISTANCE TO DISPLACEMENT IN SOLUTION

The resistance exerted on the particles by the surrounding medium when they move under the influence of a force is a means of investigation that is now often used for the determination of the size of the particles. In some cases—e.g., when a sol is filtered through a membrane of collodion or gelatine (ultrafiltration)—the connection between the resistance and the size of the particles is not known in detail, but we are justified in assuming that the resistance rises with the size of particles. The small particles are more rapidly pressed through the filter than the large ones. Certain kinds of filters transmit molecularly dissolved substances, but not colloids; an important method of separation, especially in biochemistry. If a colloid is separated from a great quantity of dispersion medium by such a membrane, the molecularly dissolved substances—the crystalloids—diffuse through the membrane, leaving a colloid of a purer state—Graham's dialysis. If the particles are spherical and move through a liquid, the resistance is $6\pi\eta rv$, where η is the viscosity, r the radius and v the velocity. If the force that causes the movement is known—e.g., gravity—the radius may be calculated.

Thus, by measuring the velocity of sedimentation, the radius can be found. We have

$$r = \sqrt{\frac{9\eta v}{2(s_1 - s_2)g}}$$

where s_1 is the specific gravity of the particle, s_2 that of the liquid, and g the gravity constant.

Even when no exterior forces are acting, the particles in a colloid solution are in movement because of the impacts from the surrounding molecules. This is the so-called Brownian movement, which has attracted so much attention of late. According to the kinetic theory of the Brownian movement, which has been fully confirmed experimentally, each particle, whatever its size and nature, has the same translatory energy as a mole-

cule—i.e., $\frac{3RT}{2N}$, where R is the gas constant, T the

absolute temperature, and N the Avogadro constant. Because of the resistance of the surrounding medium, the mean value of the quadrate of the distance traversed in the time t by the particle is $2Dt$, where D , the dif-

fusion constant of the particles, has the value $\frac{RT}{N} \cdot \frac{1}{6\pi\eta r}$.

Thus, if the displacement of the particle is measured the radius may be found. In certain cases it is more convenient to measure D directly and then calculate r by means of this experimental value.

Owing to the fact that the size of the particles is rather great in comparison with that of the molecules, colloids diffuse very slowly compared with crystalloids. As a matter of fact, Graham, the founder of colloid chemistry, regarded this property as the fundamental difference between colloids and crystalloids. We know now that between colloids and crystalloids—so very different in their extremes—there exist all degrees of transition forms and therefore all degrees of diffusibility.

The size of particles may also be determined by measuring the sedimentation equilibrium—i.e., the distribution of the number of particles per c.c. under the joint influence of gravity and the Brownian movement. In this equilibrium, the concentration of the colloid diminishes, exponentially with increasing height, as is the case with the atmosphere surrounding the earth.

Hence

$$r = \sqrt{\frac{RT}{N} \cdot \frac{\ln \frac{n_1}{n_2}}{\frac{4}{3} \pi (s_1 - s_2) g (x_2 - x_1)}}.$$

The osmotic pressure of a colloid solution is determined, as far as the colloid in it is concerned, only by the number of particles per cubic centimeter (n).

We have

$$p = \frac{RT}{N} \cdot n$$

Consequently, the osmotic pressure is a measure of the degree of dispersion. The osmotic pressure of a colloid is often determined by means of a common osmometer, provided with a membrane permeable to crystalloids, but impermeable to the colloid particles. Now, however, owing to ion absorption, the particles are, in most cases, surrounded by an electric double-layer of ions, and the colloid thus acts as an electrolyte, one ion of which is able to penetrate the membrane, but not the other. This causes complications. A so-called membrane equilibrium is formed, and the osmotic pressure found is not a real measure of the structure of the colloid.

Owing to the Brownian movement, the number of particles in every small volume of a sol undergoes spontaneous and incessant fluctuations. Hence the value of every property of the colloid in the small volume fluctuates.

This phenomenon, predicted by the kinetic theory for colloidal as well as for molecular solutions, has been the subject of extensive investigations. The results are of importance because they show that Boyle's law holds good very exactly for dilute colloid solutions, and because of the light they have thrown on the applicability of the probability calculus to a natural phenomenon. From these studies we have also obtained a deeper comprehension of the conception of entropy. For they have shown, in a direct and experimental way, that the law of the incessant growth of entropy only holds for macroscopic systems.

It often occurs that the particles of a colloid are too small to be measured directly—e.g., by means of the ultramicroscope or by determining the velocity of sedimentation. In some of these cases one can overcome the difficulty by depositing gold on the particles, thus increasing their size. This method has already been applied to sols of almost all the metals, and to sols of some sulphides. If the quantity of gold on a particle is known, it is easy to calculate the radius in the usual manner.

In most colloid solutions and precipitates there are particles of various sizes, and the investigator should, of course, be able to determine not only the mean size, but also the real structure of the sol—e.g., the law governing the distribution of the various sizes of particles.

Finally, we will consider two phenomena, the study of which does not, it is true, enable us to carry out direct measurements of the structure, but which, in spite

of that, are of great interest in judging of the structure of colloids, viz., the viscosity on the one hand, and, on the other, the adsorption and the accompanying phenomena, viz., the cataphoresis and the electric endosmose.

RELATION OF VISCOSITY TO COLLOIDALITY

The viscosity of a sol depends, in a manner not yet known, on the size of the particles, the concentration, etc., but above all on the nature of the particles. Some sols—e.g., metal hydrosol, suspensions of barium sulphate (case 1)—have a viscosity only slightly greater than that of water, but others—e.g., silicic acid hydrosol, oil emulsion gelatine solution (case 2)—have a viscosity many times greater than that of water. From the fact that suspensions with undoubtedly solid particles come under case 1, and emulsions with undoubtedly fluid particles come under case 2, the conclusion has been drawn that the fine-grained colloids under case 1 also contain solid particles and those under case 2 fluid ones. If this be the case, measurements of the viscosity would be a capital means of ascertaining the state of aggregation of the substance of the particles. Recent investigations indicate, however, that the case is far more complicated. Small particles probably have relatively thicker water coverings than greater particles, and, accordingly, the viscosity is higher in a fine-grained colloid than in a coarser one, provided the two sols have particles of the same material and are of the same concentration by weight (e.g., sulphur hydrosols). When the potential difference between particles and fluid is altered the thickness of the water-coverings should alter and, as a matter of fact, the viscosity is altered too. As the water-covering increases, the particle will act more and more like a drop of fluid in relation to the surrounding medium and will, therefore, as far as the viscosity is concerned, approach more and more to the limiting case which is represented by an oil emulsion.

ADSORPTION

The phases—two or more in number—in a disperse system have a contact surface very largely relative to the volume of the system. It is obvious that in such circumstances, adsorption differs in strength. If an electrolytically-dissociated salt is adsorbed, cations and anions are, of course, brought together at the contact surface in equal numbers, but the adsorption of the particles in relation to cations and anions is most often unequal, inasmuch as one is present in excess nearest to the surface of contact and the other in excess some way out of the liquid. The result is the formation of an electrical potential difference, a so-called adsorption potential difference or an electrical double-layer. Because of this the disperse phase, when exposed to the influence of an electric field, will migrate toward one of the poles, provided it is freely movable, as in the case of a colloid solution (cataphoresis). If the disperse phase is immovable the liquid will move in the opposite direction (electrical endosmose). By measuring the velocity of migration of the particles or the liquid under various conditions we are able to study the changes in the difference of potential and thereby in the adsorption. At least at low concentrations the adsorption may be expressed by the formula

$$y = \alpha \cdot e^{\beta}$$

where y is the amount of substance adsorbed per grain adsorbent, e the concentration in the solution of the substance adsorbed, and α and β constants depending

on the nature of both. Now, as a rule, it happens that for the two ions of a salt both α and β have different values—e.g.,

$$\alpha \text{ cation} < \alpha \text{ anion}$$

$$\beta \text{ cation} > \beta \text{ anion}$$

In the example chosen the disperse phase will with increasing adsorption become more and more negative in relation to the dispersion medium. This charge reaches a maximum and decreases to zero, at the point where the adsorption isotherms intersect, then becomes positive and increases again.

COLLOIDAL TRANSITION

The changes of state which may occur on a disperse system, a colloid, are essentially changes of structure. Of course, purely chemical reactions, too, are to be taken into consideration, but they do not play such a prominent part here as in the molecular structural systems. The greater number of the disperse systems, and those of greatest importance, too, are the ones whose disperse phase is embedded in the other phase in the form of particles; in the sequel we will only mention the changes of state in such systems. The most important change of state is the uniting together of the single particles (primary particles) into aggregates (secondary particles). Such an aggregation often occurs directly after the formation of the particles. It may stop for various reasons after the aggregates have reached a certain size. The result is a colloid with complex particles—a secondary colloid. If the aggregation goes on further we may have two extreme possibilities—with many transition forms.

FACTORS DOMINATING IN COLLOIDAL TRANSITION

First Case.—One or more of the following factors dominate—viz., (1) low hydration of the particles; (2) low number of particles per unit volume; (3) great difference in specific gravity between particles and liquid; (4) violent stirring of the system.

The characteristic of this case is that no bridges are formed between the aggregates and that, in consequence of this, they fall to the bottom after having grown sufficiently; the colloid is precipitated (e.g., coagulation of a gold hydrosol by the addition of hydrochloric acid).

Second Case.—One or more of the following factors dominate—viz., (1) high hydration of the particles; (2) high number of particles per unit volume; (3) small difference in specific gravity between particles and liquid; (4) no stirring of the system.

In this case bridges are formed between the aggregates, and the particles arrange themselves into a three-dimensional network throughout the system; the colloid gelatinizes (e.g., the coagulation of a sol of silicic acid by the addition of hydrochloric acid, the setting of a warm gelatine solution when cooling). Owing to capillary forces the liquid is kept in the network with great strength. Measurements have shown that the liquid is under a pressure of several hundred atmospheres. In many respects, therefore, the gelatinized colloid acts as a solid.

NUMEROUS TRANSITION FORMS BETWEEN THE EXTREME CASES

There exist numerous transition forms between these two extreme cases. If the particles are not bound together by bridges into a solid, but still reach macroscopical size and possess a certain loose structure, one

speaks of flocculation of the colloid (e.g., coagulation of ferric hydroxide by addition of ammonia). It may be doubted, however, if such flocculent suspensions are not to be regarded as fragments of a gel of little mechanical resistance shattered by the stirring of the liquid. In case 1 the Brownian movements alone of the particles should suffice.

CAUSE OF AGGREGATION

The most important cause of the aggregation of the particles is the decrease or the disappearance of the difference of potential between particle and liquid. This may be effected by altering the ion adsorption. Hence one of the most important means of bringing about aggregation or disaggregation is addition or removal of ions. Because of the opposite electric and coagulating action of anion and cation and their difference of adsorption there will always exist, for certain electrolytes in relation to a certain colloid, a domain of concentration within which they have a disaggregating action. If a solely aggregating electrolyte is added to a colloid in increasing doses (e.g., hydrochloric acid to a gold hydrosol), the velocity of aggregation first rises rapidly with concentration, then more slowly and reaches a constant maximum value. Let us make the assumption that within the latter region every mutual approach of two particles to a certain limit leads to aggregation, but within the former region only a certain fraction of those approaches. Then it is possible to develop, on the basis of the laws of the Brownian movements alone, a mathematical theory for the kinetic of aggregation.

With regard to the aggregation by electrolytes it has, in addition, been found that inorganic ions of the same valency generally aggregate equally strongly if added in equivalent amounts. This is due to some extent to their being nearly equally strongly adsorbed. When the valency of the aggregating ion increases, the aggregating effect rises very rapidly. The concentrations of the ions K^+ , Ba^{++} , Al^{+++} required to aggregate particles of As_2S_3 to the same degree show the mutual relations: 1, 1/20, 1/1000. Thus the three-valent Al^{+++} has an aggregating power 1,000 times greater than the monovalent K^+ . These circumstances are closely related to the course of the adsorption isotherm, but are not yet quite clear.

The aggregation may be reversible or irreversible—i.e., in certain cases disaggregation may be effected—in others not. Some colloids (e.g., metal hydrosols) are difficult to disaggregate, others (e.g., sulphur hydrosols) are easy. Certain ions nearly always bring about irreversible, others reversible aggregation. The question of irreversible or reversible coagulation is probably closely connected with that of the hydration of the particles. Thus particles which hold much water around them are easily disaggregated. The water-covering prevents the particles from uniting too closely together.

PROTECTIVE COLLOIDS

The aggregating effect of an electrolyte may often be reduced to a very great extent by the addition of a small quantity of a suitable colloid of another kind only slightly sensitive to electrolytes, a so-called protective colloid—e.g., gelatine to a gold hydrosol. As a rule the electric charge of the protective colloid should be of the same sign as that of the colloid to be protected. The mechanism of this protecting action is still but very incompletely known. Most probably the particles of the protective colloid become attached to the particles

of the other colloid and the aggregate resulting from this obtains a good deal of the stability toward electrolyte which characterizes the protective colloid. Colloids of opposite electric charge precipitate each other mutually (e.g., the negative Sb_2S_3 and the positive Fe_2O_3) provided there is not too great an excess of either of them, in which case no precipitation will occur. This is obviously entirely analogous to the action of the ions. Such mutual colloidal reactions are of great importance in the economy of nature and in industry.

In the preparation of easily aggregated colloids a protective colloid is often added in order to maintain the primary structure. Thus the particles of a metal hydrosol, if formed in the presence of a small quantity of a protective colloid, are kept apart even when the sol is evaporated to dryness. The dry substance can be redissolved in water without any perceptible change of structure taking place (e.g., commercial colloid silver).

OTHER STRUCTURE CHANGES

A change of structure that plays a part, formerly a little over-rated, in colloid solutions with comparatively easily soluble particles is the growth of the larger particles at the expense of the smaller ones. In a suspension of calcium sulphate this change of structure is clearly visible, but in the more sparingly soluble barium sulphate the process goes on at an extremely slow rate. Formerly, aggregation, especially the irreversible process, was often interpreted as a recrystallization. In irreversible aggregates as well as in compressed powders there gradually take place association and crystallization phenomena which may greatly change the structure of the system (e.g., silver crystals in sediments from silver colloids).

Processes of the latter kind play a prominent part, especially in gelatinized colloids. On the whole, a great variety of changes in structure and accompanying processes may occur in gels. When gradually deprived of water the gel of silicic acid, for instance, goes through a series of states, some of which differ rather decidedly from others. The nature of these processes is not yet known. A gelatine gel probably consists of particles with a high percentage of "dry substance," and a liquid with a low percentage. In sol-formation water is supposed to pass over from the liquid to the particles, the particle-associations being thereby disintegrated; in the gel-formation the particles lose water.

The study of the structure of gels is a rather difficult one. The particles of most gels do not contrast optically to any great extent with the surrounding medium, and consequently the ultramicroscope is not able, as a rule, to make their primary particles visible. Moreover, these are often packed together so closely that they cannot be distinguished from one another optically. On the other hand, we have been able to study with more success the macroscopic properties of the gels in chemical and physical respects. The elastic gels, especially gelatine, collodion, celluloid, rubber, etc., play a prominent part in industry, and their investigation is, therefore, a matter of great importance.

University of Upsala, Sweden.

Leather Industry Establishes Research Laboratory

Under the auspices of the Tanners' Council of the United States the American Leather Research Laboratories will be established at the University of Cincinnati. G. D. McLaughlin will be in charge.

Legal Notes

BY WELLINGTON GUSTIN

Vessel of Paper United by Fused Cement Not Patentable

The United States Circuit Court of Appeals at Detroit has held that the Harbeck patent, No. 1,062,002, claim 1, for a vessel having walls made of layers of paper united to each other by a fused cement, was void for anticipation, the claim of invention being old in the art at the time Harbeck claimed he made the discovery.

The claim of the patent was on the use of a fused cement to unite sheets of paper into duplex board, practically impervious to moisture, grease and aroma. The court found that the use of fused cement for the purpose of uniting sheets of paper into duplex board was old in the art, having been used for similar purposes and known commercially for more than two years prior to the date Harbeck's application for patent was filed, and therefore the use of this material by a can company in the manufacture of its cans was not invention, but a matter of mechanical skill and judgment.

Salesmanager of Chemical Company May Not Alter Contract of Company Without Authority

A new trial has been awarded by the Court of Errors and Appeals of New Jersey to the Interstate Chemical Co. in its action against the James Leo Co. The chemical company brought this suit to recover for breach of contract, in writing, by which the seller, the James Leo Co., agreed to deliver 10,000 folding boxes, as per sample submitted. The buyer, the chemical company, claimed that by reason of the failure of the seller to deliver the boxes, as per the order, it was obliged to go elsewhere in the public market to purchase the boxes at a far greater price than that fixed in the contract, and that it sustained a further loss by reason of the failure of the seller to carry out its contract and make delivery of the boxes.

The seller claimed a set-off for the value of the labor performed and materials furnished in and about the boxes, and charged that the contract had been modified by the buyer agreeing to take boxes in one color instead of two, and that the buyer had refused to accept the boxes under the modified contract.

Upon trial judgment was given for the seller on its counterclaim, and the Supreme Court of New Jersey affirmed this judgment. On appeal to the Court of Errors and Appeals the first question presented was whether the salesmanager of the chemical company had any authority to alter the terms of a written contract made by his principal, the chemical company. The court said there was no attempt to prove he was so expressly authorized, and that the mere fact of his being the salesmanager gave him no such authority.

The second question was whether the salesmanager was held out by the chemical company as authorized to make this change in the original contract. Now the rule is that where one holds out another as his agent one is bound the same as if express authority has been given. It did not appear that the salesmanager had ever before attempted to change any original contract for the company.

Again it was urged that the chemical company had by its actions subsequently ratified the contract as modified by its salesmanager. The court found that it had no knowledge of the change in the contract until an attempt was made by the James Leo Co. to deliver the boxes all in one color. Ratification by principal of acts of an agent implies that the principal had knowledge of the facts and acquiesced in them.

Court Holds Seller Under the Contract Could Have Others Manufacture the Products

The Court of Errors and Appeals of New Jersey has affirmed the judgment in the action brought by the National Metal Stamping & Manufacturing Co. against the Associated Rolling Mills, Ltd., appealed from the Supreme Court.

The action arose out of a sales contract. The rolling mills contended that at the time of the execution of the agreement it was not in the contemplation of the parties that the National company would have the products called for made by other manufacturers and thus obtain the advantage of their cheaper method. And because nothing on this question appeared in the contract the rolling mills contended that the company was bound to manufacture the articles itself, though it might cost more than they were to receive from the buyer.

The court comments that the buyer must have been extraordinarily ignorant of human nature if it did not in fact contemplate that the seller would seek the cheapest possible way of fulfilling its contract. And if it did not contemplate such when the contract was made, the court said that it must be held bound under the law to contemplate that the seller would pursue the course usual with prudent business men.

United States Supreme Court Holds Virginia Tax Unconstitutional

The United States Supreme Court has reversed the judgment obtained by the State of Virginia against the F. S. Royster Guano Co. of Norfolk. The latter operates a fertilizer plant in Norfolk County, Va., and several plants in other states. During 1916, the company made net profits from the operation of its plant in Virginia amounting in round figures to \$260,000; and from its plants in other states the net profits were about \$270,000. Under the revenue law of the state the guano company returned for taxation as income the former amount, omitting the latter. Under appropriate provisions of the state law, the state officials added the latter amount, and assessed an income tax against the company upon the total.

The company then asked the court at Norfolk for relief from the tax on the \$270,000 for the reason that the state law, in taxing that part of its business which was transacted outside of the limits of Virginia, imposed upon it a burden not placed upon domestic corporations doing no part of their business in Virginia but transacting business beyond the limits thereof, such corporations being expressly exempted from a tax on income derived from business done without the state limits; the state laws thus denying to the company the equal protection of the laws, in violation of the Fourteenth Amendment of the U. S. Constitution.

The court at Norfolk sustained the tax law and this judgment was affirmed by the Virginia Supreme Court of Appeals. The guano company then appealed to the Supreme Court of the United States. This court has said the imposition of tax on income from sources out-

side the state is invalid, where corporations doing no business within the state are not taxed. It says the Virginia law (Acts Va. 1916, ch. 472) in so far as it imposes on a domestic corporation doing business both within and outside the state a tax with respect to its income derived from sources outside the state, denied such corporation the equal protection of the laws, in violation of the Fourteenth Amendment, in view of the statute (Acts Va. 1916, ch. 495) exempting domestic corporations doing no part of their business within the state from any tax on their income; the classification of the property taxed not being reasonable, but arbitrary, not resting upon any ground of difference having a fair and substantial relation to the object of the legislation, so that all persons similarly circumstanced shall be treated alike.

While the latitude of discretion is wide in the classification of property for purposes of taxation, a discriminatory tax cannot be sustained against the complaint of a party aggrieved, if the classification is altogether illusory, said the court.

Manufacturer Must Account for Royalties

An appeal from an order to render an accounting by the Belmont Packing & Rubber Co., formerly known as the Clement Restein Co., unto Norman B. Miller has been dismissed in the Supreme Court of Pennsylvania. It appears that Miller sued the company and recovered a verdict, upon which the order for an accounting was entered, and the appeal was taken.

Plaintiff alleged that he contracted orally with the corporation by which the latter was to pay him 3c. a lb. on all "piston rod packings manufactured and sold by defendant" under certain patent rights which plaintiff had assigned to it, until the expiration of such patents; that the assignments were made, first, for a square hole piston rod packing, and next, for a round hole piston rod, relying upon the oral promise of payment in royalties; that large quantities of the patent article have been sold by the company without an accounting for the royalties due.

The company admitted the assignment of the patent rights, but denied having made any oral or written promise to pay compensation therefor. Mr. Restein, president of the company, testified that both he and Miller worked on the inventions "for the benefit of the company," but it appeared that Miller was the inventor of the patented articles. The rule of law as stated is that one who accepts and continues to take and retain the benefits of an agreement cannot be heard to deny the authority of the agent who acted for him in making the agreement. Restein was thus held to have authority to make the royalty contract as alleged, and the company receiving the benefits from the assignment is liable for the royalties, and the obligation to pay the royalty subsisted so long as the company continued to sell the articles.

In the absence of a contractual stipulation to the contrary, the obligation to pay the royalty would continue, and, after a reasonable time, on demand, the company would be bound to account to the inventor for the sales made by it, the reasonableness of the time being a question to be determined by court or jury.

The assignment contract mentions the sum of \$1 as the consideration for the assignment of the patents, but the court held that such did not prevent the inventor or assignor from showing the real consideration for the patent rights.

Engineering Problems in Dust Explosion Prevention

Causes and Factors Affecting Dust Explosions — Types of Industrial Plants Affected — Ignition Temperatures — Propagation and Velocity of Flame — Pressures Developed — Relation of Humidity — Prevention

By DAVID J. PRICE*

AT THE present time the prevention of dust explosions is commanding the earnest attention of engineers of all classes both in the United States and abroad. This is quite natural, since many engineering problems have been developed in the study of dust explosions, their causes and prevention. Before these explosions can be prevented, it is necessary to understand fully their nature and behavior. This means a determination of the various causes and circumstances under which dusts may be ignited; the manner in which the explosion spreads or propagates; the ignition temperature of the various dusts; the pressure that will be developed during the explosion, and also the effectiveness of any methods which may be designed for prevention.

It is not the intention to consider in this article the simple causes that have been established since the study of grain dust explosions was undertaken by the Federal Government. It is well known that disastrous explosions have resulted from the ignition of flammable¹ dusts by matches, open flames, lanterns or torches. The attention of engineers at the present time should rather be directed particularly to the mechanical causes, especially those which occur during the handling of organic materials.

TYPES OF INDUSTRIAL PLANTS

In order to understand the nature and extent of dust explosions it is essential that consideration be given to the kind of industrial plants in which these explosions are occurring.² Dust explosions have occurred most frequently in plants where grain or grain products are either milled or handled, such as grain elevators, flour mills, feed and cereal mills and starch factories. Disastrous explosions have occurred also in sugar refineries, cocoa and chocolate plants, candy factories, spice works, wood-working establishments, paper mills and printing plants, shoe factories, fertilizer works, cork-grinding plants, drug and herb works and similar types of industrial plants where dusts are created. Explosions of aluminum and magnesium dusts have also taken place. Many disastrous smut and grain dust explosions have occurred in threshing machines in the Pacific Northwest, while a large number of fires have also occurred in cotton gins during the ginning process.

Since May, 1919, a series of very disastrous explo-

sions have occurred in the United States and Canada, resulting in the death of over eighty-eight persons, injury to a large number, and property damage in excess of \$7,000,000. Three of these explosions have occurred in grain elevators, one in a feed mill, one in a starch factory and two in flour mills. In the starch factory explosion forty-three lives were lost and over \$3,000,000 damage was done. Fourteen lives were lost in one grain elevator explosion and ten in another, both explosions being very violent and doing extensive damage to property. In an explosion of "aluminum dust"³ in a Northwestern factory six girls lost their lives and as many others were injured. A recent explosion of "hard rubber" dust in a Michigan plant resulted in the death of eight workmen and has attracted considerable attention.

IGNITION TEMPERATURES OF GASES AND DUSTS

From the experimental work which has already been conducted it appears that a dust explosion is very similar to a gas explosion. Although particles in a dust cloud are larger than the minute molecules in a gas mixture, yet the nature and behavior of a dust explosion appears to be very much the same as a gas explosion. To produce a gas explosion it is necessary that a proper mixture of gas and air and a source of ignition be present. The same condition exists in connection with producing a dust explosion. It is as impossible to produce a "spontaneous" explosion with dust as it is with gas. In both cases the explosive mixture must be ignited by some external source of heat or flame.

In order to obtain some idea as to the relation between dust explosions and gas explosions it will be of interest to note the ignition temperatures of the more common flammable gases in air as determined by Dixon and Coward.⁴

Gas	Ignition Temperature Deg. C.
Carbon monoxide.....	644 to 658
Hydrogen.....	580 to 590
Ethylene.....	542 to 547
Methane.....	650 to 750
Ethane.....	520 to 630

A series of experiments was conducted by R. V. Wheeler, chemist attached to the Explosions in Coal Mines Committee of England. In the first series of tests an effort was made to determine the temperature at which the dust would ignite and propagate flame. A second series of tests was conducted to determine the lowest temperature at which ignition could be effected. The following results were obtained:

Kind of Dust	Ignition Temperature, Deg. C.	Temperature of Flame Propagation, Deg.
Dextrine.....	540	940
Sugar.....	540	805
Starch.....	640	960 to 1035
Flour.....	650	1060
Grain.....	630	995 to 1050

*Engineer in charge Grain Dust Explosion Investigations, Bureau of Chemistry, U. S. Department of Agriculture, Washington, D. C.

¹The National Fire Protection Association, the National Safety Council and similar organizations are now using the word "flammable" instead of the old word "inflammable." Some persons have misinterpreted inflammable, thinking of the first two letters of this word as the prefix *in* whose meaning is *not*, as in inactive (not active), or incombustible (not combustible). Flammable is shorter, more definite and cannot be misunderstood. The negative of flammable is non-flammable.

²The study of the cause and prevention of coal dust explosions is being undertaken by the Bureau of Mines, United States Department of Interior, while the work pertaining to the cause and prevention of dust explosions in industrial plants is being carried on in the Bureau of Chemistry of the Department of Agriculture.

TYPICAL INDUSTRIAL CONFLAGRATIONS

Fig. 1. A large grain elevator in New York harbor being destroyed by fire following dust explosion. Sufficient grain was lost to supply bread rations for 200,000 men for one year.

Fig. 3. Grain elevator, Port Colborne, Canada, at entrance to Welland Canal, badly damaged by grain dust explosion, resulting in loss of ten lives.

Fig. 2. A starch factory in Iowa completely destroyed by starch dust explosion. Forty-three lives were lost and \$3,000,000 property damage was done.

Fig. 4. A sugar refinery badly damaged by explosion of sugar dust. Twelve lives were lost and sugar stocks were destroyed.

Wheeler states in his report that sugar and dextrine appeared to be the most flammable of all the dusts, the temperature at which ignition could be effected being 540 deg. C., a temperature well below red heat. It is interesting to contrast this low temperature with the ignition temperatures of the gases given above, from which it will be noted that the ignition temperatures of sugar and dextrine are lower than methane, carbon monoxide and hydrogen, ranging with ethane and ethylene. Most of the remaining dusts have practically the same ignition temperature, 600 to 650 deg., thereby ranging with the other gases.

When the Federal Government began the study of dust explosions attention was directed to a determination

of the ignition temperatures of the various dusts and the methods and conditions under which these dusts propagated flame. With the apparatus used in the tests, the following results were obtained:⁵

Kind of Dust	Ignition Temperature Resulting in Propagation
Wheat elevator dust.....	1295 C. equals 2363 F
Flour.....	1265 C. equals 2300 F
Oat and corn elevator dust.....	995 C. equals 1821 F
Oat hull dust.....	1020 C. equals 1868 F
Yellow corn dust.....	1025 C. equals 1877 F

⁵Preliminary Report on the Explosibility of Grain Dusts. Co-operative Investigation by Millers Committee, Buffalo, N. Y., under the direction of Dr. George A. Hulett, chief chemist, Bureau of Mines, U. S. Department of the Interior, by David J. Price, engineer in charge, and Harold H. Brown, assistant chemist, Grain-Dust Explosion Investigations, Bureau of Chemistry, U. S. Department of Agriculture. Copies no longer obtainable.

From the many theories which have been advanced in the effort to explain the action that takes place during the progress of dust explosions, two appear prominently: (1) That a distillation of flammable gases occurs when the dust becomes heated, resulting in an explosion; and (2) that the explosion is nothing more than a rapid communication of flame or fire from one particle to another, depending to a large degree on the fineness of the dust. That is, the finer the dust and the lower the moisture content the more rapid the propagation and therefore the greater the violence accompanying the explosion. This would seem to establish very definitely a relation between fire and explosion.

In connection with the investigation of a large number of explosions and fires in grain threshing machines in the Pacific Northwest, the Department investigators made the following determinations:⁶ In 117 cases observed 95, or about 80 per cent, were sudden, violent explosions, and the remaining 22, or 20 per cent, were merely fires. This would seem to indicate that in the majority of cases the explosions were accompanied by violence, while in the others the fire had not advanced to a point where it assumed the proportion of an explosion.

In the 95 cases referred to it was felt that the explosion might be classified either as sudden and violent, or as slight and muffled in nature. The same phenomenon has developed in connection with dust explosions in industrial plants. In many cases a primary explosion, which is nothing more than a small puff, is followed by fire in which the property is extensively damaged or destroyed. In other cases a series of explosions follows, becoming more violent as it progresses, destroying both life and property. This would seem to indicate very definitely that if the dust is present in the plant to feed the original flame, an explosion follows. In plants where little dust is in suspension and where "good housekeeping" is practiced, the occurrence merely assumes the proportions of a fire and no violent explosion results. Reference is made to this phenomenon at this time to emphasize the fact that a disastrous dust explosion may occur during the course of any fire if sufficient combustible dust is present in the plant to feed the flame and allow it to propagate. The dust that accumulates throughout the plant is thrown into suspension by slight concussion, with the result that the primary "ignition" or explosion develops into a secondary explosion of large proportions.

VELOCITY OF FLAME

Experimental work has been conducted to determine the velocity or rate of flame travel in dust explosions. It is understood that the rate of propagation or flame travel in a gas explosion depends upon two factors: (1) The flammability of the gas, and (2) the amount of gas present. For instance, the explosive limit of methane gas ranges from 5½ to 14.5 per cent,⁷ with 9.6 per cent as the most flammable mixture. With this latter percentage the rate of flame travel is the most rapid and the explosion most violent. The rate of flame travel in dust explosions depends also on (1) the flammability of the dust, and (2) the amount of dust in suspension. In some of the early reports of the Bureau of Mines it is stated that the average velocity of flame in coal dust explosions is 2,270 ft. per second. British investigators

report 2,114 ft. per second, while in French experiments 3,300 ft. per second has been obtained.

The maximum velocity of propagation of flame in many gaseous mixtures has been determined with accuracy. The following results have been obtained:

Gaseous Mixtures	Velocity, Feet per Second
Hydrogen, $2H_2 + O_2$	9,250
Ethane, $C_2H_6 + 3O_2$	7,724
Methane, $CH_4 + 2O_2$	7,616
Carbon monoxide, $2CO + O_2$	5,510

The velocity of propagation in explosions through most gas mixtures is more rapid than through most dust clouds, although in a few cases it has been found that the velocity of flame propagation in coal dust explosions has exceeded the maximum for certain gases. In only two tests has any attempt been made to measure the velocity of propagation of the flame in clouds of materials other than coal dust. One indicated that the velocity through a cloud of wheat flour dust was practically the same as through coal dust; the other that the propagation through a cloud of powdered starch was several times as rapid as through coal dust. The results, however, cannot be considered to be conclusive.

PRESSURES DEVELOPED BY DUST EXPLOSIONS

In connection with the determination of the ignition temperatures and the relative ease of flame propagation of dusts an effort has been made to determine the pressures developed during the progress of the explosion. In the large-scale tests that have been conducted the Bureau of Mines reports a pressure of 103 lb. per sq.in. with coal dust. British investigators report pressures ranging from 100 to 120 lb. per sq.in. Taffanel, a French investigator, reports pressures of 227 to 270 lb. per sq.in. He states that in one test at the steel gallery an established pressure strength of 227 to 270 lb. per sq.in. was maintained and that pieces of steel were thrown up a distance of 150 m., or 472 ft.

Much work to determine the relative flammability of the various dusts has been done by both the Bureau of Mines and the Bureau of Chemistry. After a series of extensive experiments the following results, based on the use of 75 mg. of dust in the standard laboratory apparatus, were obtained:⁸

Kind of Dust	Pressure Generated Lb. per Sq.In.
Lycopodium.....	17.5
Wheat smut dust.....	15.9
Yellow corn.....	15.2
Dextrine.....	14.6
Tanbark.....	13.3
Wheat elevator dust.....	13.0
Wood dust.....	12.8
Corn starch.....	12.7
Sugar.....	12.2
Potato flour.....	11.7
Fertilizer.....	10.5
Coal (Pittsburgh).....	10.1
Cocoa.....	9.1
Sulphur.....	8.8
Cork.....	7.4

From these results it might be concluded that the grain dusts are more flammable than Pittsburgh standard coal dust. This has been confirmed by large-scale tests which indicate that flame propagates through a cloud of grain dust more easily and with a more violent explosion than through a corresponding amount of coal dust.

In very recent tests conducted in co-operation with the Bureau of Mines in the steel galleries at Bruceton, Pa., it was found that flour and coal dusts acted similarly. Starch dust propagated more rapidly, produced

⁶U. S. Department of Agriculture, Bulletin 379, p. 5.

⁷U. S. Bureau of Mines Technical Paper 150, p. 6.

⁸Journal of Industrial and Engineering Chemistry, vol. 9, No. 3, p. 269.

higher pressures, and did a great deal of damage to the steel galleries used in the tests.

It has already been stated that dust must be present in suspension in proper proportions before an explosion can occur. Efforts are being made in the experimental work to establish these proportions, as has already been done in connection with the gas mixtures. In some of the tests conducted results were obtained when one-twentieth grain, or 0.00176 oz., of dust was put in suspension in 1,400 c.c., or 85.36 cu.in., of air. To obtain the same proportion of dust in air and render the mixture as flammable as that used in the laboratory test it would be necessary to have only 10 lb. of the dust in a closed room containing 4,466 cu.ft., or a room 10 x 30 x 15 ft.

The first dust explosion to attract attention in this country occurred at Minneapolis in 1878. Professors Peck and Peckham of the University of Minnesota conducted experimental work in the investigation which followed the explosion. In this investigation it was found that by blowing 2 oz. of dust upon an open flame in a box containing 2 cu.ft. of air sufficient pressure was developed to lift two men standing on the cover.⁹ This would mean diffusion at the rate of 1 oz. of dust to 1 cu.ft. of air space. Their report states that a sack of flour and 4,000 cu.ft. of air will generate force enough to throw 2,500 tons 100 ft. high.

The Bureau of Mines reports that explosions could be produced when only 0.032 oz. of coal dust was suspended in 1 cu.ft. of air, or 1 lb. in 500 cu.ft. It was found in order to produce complete combustion all the oxygen in 1 cu.ft. of air was required to burn 0.123 oz. of the dust used.

In the French experiments conducted by Taffanel an instance is cited when the low weight of 0.023 oz. of dust per cu.ft. of space was sufficient to produce an ignition.

Experimental work is now in progress to determine definitely the smallest amount of dust in suspension per unit area through which an explosion can propagate.

RELATION OF HUMIDITY TO EXPLOSION FREQUENCY

The relation of humidity to the frequency of dust explosions has been markedly noticeable in the investigational work. This is especially true in connection with explosions where static electricity has appeared as a probable cause. In the large number of thresher explosions in the Pacific Northwest, which comprises the inter-mountain territory between the Cascade and Rocky Mountain ranges, it was found that in 128 cases 86 explosions, or 70 per cent of the total, occurred between the hours of 1 and 7 p.m., when the humidity was extremely low. The range of humidity was usually from 6 to 17 per cent. These explosions have occurred in grain separators during the threshing of wheat containing smut dust. In 112 explosions from 1 to 35 per cent of the heads of wheat being threshed were smutted. In 108 cases the average smut percentage was 15.

A study of fires in cotton gins in certain sections of the South developed the same relation. Although this relation has not been definitely determined in industrial plants it is reasonable to conclude that the dust explosion hazard is greater during periods of continued low humidity.

This article has been confined largely to the theory of dust explosions together with the causes and factors

affecting these explosions. An article is now in the course of preparation dealing with the methods of prevention that have been developed and proved effective, and also the chemical engineering research problems demanding attention.

Wood Pipe in the Chemical Industry

The accompanying illustration shows a system of towers for the collection of hydrofluoric acid from acid phosphate manufacture at the plant of the Jarecki Chemical Co., Cincinnati. This pipe was manufactured and installed by the Michigan Pipe Co., of Bay City, Mich. The layout is composed of three vertical towers of 48-in. inside diameter, the acid gas

WOODEN TOWERS FOR HYDROFLUORIC ACID

main being 30 in. inside diameter and the special wood elbows and tees also constructed of 30-in. pipe. The gases are drawn from the bottom of tower 1 to the top of tower 2 through a 32-in. specially mortised pipe connection. Draft is created by the exhaustor at the bottom of tower 2. This type of construction is becoming general in the fertilizer industry and pipe may be made in any lengths desired up to 16 ft., being constructed of 3-in. thick Canadian white pine staves, double-tongued and grooved on the lateral edges and molded on the inner and outer faces to conform with the inside and outside diameter of the pipe. Each section of pipe is mortised and tenoned so that it may easily be set in place. The towers are tightened by the $\frac{3}{4}$ -in. rod placed 10 in. apart, excepting at the joints, where the spacing is 4 in. to provide extra strengthening.

Glare vs. Light Diffusion in Industrial Lighting

All large industrial organizations know the necessity of coating the interior of their plants with a white finish of some type to obtain improved light distribution, lower power bills and maximum efficiency from their employees. To accomplish this it has been the custom to paint the walls and ceilings of the plants with a Gloss Mill White. This was soon found, however, to be unsatisfactory, as the shiny surfaces acted as so many mirrors reflecting the light in a glaring manner and causing eye strain to develop among the employees. The Sherwin-Williams Co. spent year

⁹*Chemical Engineer*, March, April, May, 1908.

in research and consulted with some of the leading authorities on illuminating engineering and industrial plant maintenance in an effort to overcome this difficulty. The research work was not confined to reflection values alone, but much time and money were spent in getting the proper combination of pigments and vehicle to produce the desired results. Special mixtures were necessary to get just the right finish, wearing qualities and minimum absorption. As a result the exact point between the two extremes of Gloss Mill White and Flat Matte surface was determined to give the most efficient light distribution and a new paint product known as Eggshell Mill White was evolved. This product, instead of reflecting the light, disperses and diffuses it uniformly throughout the plant, thus emitting a soft, pleasant light restful to the eyes instead of the irritating glare of the high gloss surface. Another advantage of this new product is the fact that less coats are required to give the same results, thereby reducing costs for time, labor and material.

Small Type Locomotive Crane for Industrial Use

Many of the larger companies during the past few years have found it economical to handle a large part of their materials by locomotive crane. This has been necessary because of the large tonnage handled and because the crane is so much more economical than hand labor. Up to the present time, however, most of these cranes were large-capacity machines and too big to be economical in some of the smaller plants.

The saving effected by cranes at these larger plants has created a demand for a smaller type which can be used economically where there are not so many or so

SMALL TYPE OF STEAM LOCOMOTIVE CRANE EQUIPPED WITH GRAB BUCKET

heavy loads to be handled. With the idea of filling the need for a smaller capacity high-grade crane for this work, a new Brownhoist locomotive crane has just been placed on the market by the Brown Hoisting Machinery Co. of Cleveland. This machine can be changed in a few minutes' time to handle grab bucket, bottom block or magnet. With these attachments almost all kinds of materials can be handled.

Experience with the larger type locomotive cranes has proved them to be well fitted to handle ore, coal, crushed stone, etc., by bucket. With bottom block

all kinds of sling loads are handled. With magnet the cranes handle pigs, scrap, bars or castings. This new crane will do the same work as the larger types within its capacity. It is built to handle a 1-yd. bucket, hook loads of five tons, or a 36-in. magnet.

In order to meet the different working conditions, these new Brownhoists are made to operate by steam, electricity or gasoline engine. They are built for use on railroad trucks, traction wheels or creeper trucks.

Synopsis of Recent Chemical & Metallurgical Literature

Electric Purification of Fumes and Gases.—A lengthy description of the Electric Purification of Fumes and Gases is given by A. DELASALLE in the September, 1920, issue of *Chimie et Industrie*.^{*} The theory of electric purification is summarized: When a very small spherical particle of radius r suspended in a gas of viscosity a and possessing an electric charge e is placed in an electric field of intensity H , this particle will be displaced in the direction of the field with a velocity which depends on the intensity of the field and the mobility of the particle in the gas, and whose value, according to the author, is given by $V = KH$ in which K is the coefficient of mobility.

Prof. Pascal conducted a series of experiments to determine the values of K for the case of sulphuric acid particles. The tests were made with electrodes of smooth wire and with asbestos thread covered wire so as to increase the emissive power of the electrodes.

He found that K varies with the temperature as shown in the following table:

Temp. Deg. C.	Value of K
24	2.4×10^{-4}
32	4.9×10^{-4}
52	13.6×10^{-4}
55	15.1×10^{-4}

He also found the values of the radius r of the droplets as being between 0.8×10^{-4} and 5.5×10^{-4} cm. The conclusions reached are:

The gradient of a convenient potential corresponding to the point where the intensity begins to increase rapidly is in the neighborhood of 4,000 volts per cm.

The phenomenon is independent of the wave frequency; at least the result was the same for frequencies between fifteen and forty-five periods per second.

The separation of the acid in the fumes is especially a function of the wave amplitude.

Asbestos-covered electrodes do not present any advantages, especially with liquid particles, due to the fact that the humidity soon nullifies the effect of the downy surface.

It is advantageous to have the emissive electrodes of very small radius of curvature and the receptive electrodes of high radius curvature and as smooth as possible.

The use of chambers of masonry is to be avoided in treating fumes containing acid droplets.

After describing the apparatus used for the produc-

^{*}"L'Épuration électrique des fumées et des Gaz dans le service des poudres pendant la guerre," A. Delasalle, *Chimie et Industrie*, September, 1920, pp. 291-316.

tion of rectified current and the Gaillard precipitator, the author outlines the calculations of an appropriately sized apparatus and how he applies these calculations mathematically and graphically to compare the action of tubes of different diameter. He arrived at the conclusion that there is no great advantage in using very high potentials and cites the fact that even in America where potential differences as high as 250,000 volts are employed, in treating sulphuric acid fumes not over 70,000 is used. (War time conditions in France limited the experimentation voltage to about 42,000 volts.)

Tests were also made to determine the influence of the radius of curvature of the emissive electrode, and it was found that the precipitation increases gradually when the radius of curvature of the axial electrode decreases.

A series of tests on the influence of the tension and polarity of electrodes with tubes of varying diameter are also described and tabulated. The reinforcement of the intensity of the field for a given tension by approaching the electrodes has also been studied so as to verify certain points of the Badische Anilin- and Soda-Fabrik and G. A. Krause patents.

Tests were made with precipitation tubes having electrodes of small diameter (30/10 mm.) at the entrance of the gas and then 80 mm. tube concentric in one of 200 mm.

The reinforcing of the axial electrode was obtained by a cylinder having a rounded form at both extremities sliding on the 30/10 wire. This arrangement was decided upon in order to determine the length giving the maximum of precipitation and to find out whether it was possible to diminish the length of the receiving tube.

With a receiving tube of 3 m., 42,000 volts and with the same velocity of the gases the results obtained are shown in the following table:

Length of the Wire 30/10 mm.	Length of 80 mm. Cylinder Concentric to the 200 mm. Cylinder	Visual Percentage of Precipitation
3.0	0.00	90
2.7	0.30	95
2.5	0.50	97
2.0	1.00	95
1.0	2.00	90
0.5	2.50	80

Tests with stoneware receiving cylinders were made with a 150 mm. diameter tube constituted of five sections each of which was 0.65 m. high gave the following qualitative results:

Efficacious Rectified Potential Volts	High Tension Intensity Amperes	Approximate Velocity of the Gas Meters per Second	Visual Percentage of Precipitation
28,200	4.5×10^{-3}	4.6	55
29,200	4.5×10^{-3}	3.0	85
32,200	4.5×10^{-3}	3	90

The apparatus used for the experimentation and their modifications are fully described and illustrated, and the results of fifteen general tests tabulated. The author then describes the research work as applied to the purification of the sulphurous gases in roasting pyrites, giving the apparatus used, the testing conditions and the tabulated results. He concludes with the statement that the coefficient of mobility of the dust is about 40×10^{-4} at 230 deg. C. and 57×10^{-4} at 310 deg. C. with a negative electrode of 20/10 mm., and that it is absolutely necessary to have the gases at a temperature as high as possible.

Purification of Acetone.—It is known that acetone forms with carbon disulphide a mixture whose boiling point is about 39 deg. C., the boiling point of acetone being only 22 deg. C., and that the impurities in the acetone, with the exception of methylal and methanol, do not form such mixtures with carbon disulphide. J. DUCLAUX and A. LANZENBERG have used this property for the purification of acetone. (*Bulletin de la Société Chimique de France*, Oct. 5-20, 1920, pp. 779-782). The acetone to be purified is mixed with carbon disulphide in the proportion of 1 vol. acetone and 1.7 vol. CS₂ (by weight 1 acetone to 2.8 CS₂). The mixture is submitted to fractional distillation. The elimination of methylal is based on the property that the boiling point of the mixture methylal-CS₂ is 31 deg. C., whereas the boiling point of methylal is 42 deg. C. The fraction passing at about 31 deg. is the mixture methylal-CS₂. The fraction passing between 38 and 40 deg. C. contains the mixture acetone-CS₂ and some methanol-CS₂, as the boiling point of this last mixture is about 37.5 deg. C. The methanol is separated by treating the fraction with potassium carbonate. A compound, probably methyl-xanthogenate, is formed which when dissolved in water is precipitated by copper sulphate. A mixture containing 90 acetone and 10 methanol when thus treated gave a mixture containing only 4 methanol. By repeating the operation the separation of the methanol can be practically complete. The remaining pure acetone-carbon disulphide mixture is washed well with water to extract entirely the acetone. The wash water is rectified and the product obtained is practically pure acetone.

Contribution of Chemistry to Aeronautics.—The September, 1920, issue of *Chimie et Industrie* contains an excerpt of Prof. CHARLES MOUREU's work on chemistry and the war, with reference to the contribution of chemistry to the aeronautic industry. The author passes in review the production of the various materials used. Thus:

Hydrogen. The hydrogen used for filling balloons was obtained by three methods, namely: (1) By electrolysis. The resulting 98 per cent pure hydrogen was passed over palladium in quartz tubes heated to 650 deg. C., giving a 99.97 per cent pure hydrogen. (2) By the action of silicon on alkaline solutions. Captain Lelarge has used the principle, first given by Berzelius (1823), that silicon is attacked by caustic soda or potash, giving the acid silicate NaHSiO₃ with liberation of hydrogen. The hydrogen he obtained was very pure. Although the cost of production by this method was higher than by electrolysis, it had the great advantage that it could be produced where needed. (3) By fermentation. In the biochemical process for the production of acetone great quantities of hydrogen and carbon dioxide are formed. The carbon dioxide is separated by liquefaction or absorbed by an alkaline solution and the remaining hydrogen is ready for use.

Helium. After passing in review the history of helium since its discovery during the sun eclipse in 1868, he describes the advantages it presents for filling balloons and the work done in the United States for the extraction of helium from natural gas. At present a French commission headed by Prof. Moureu is studying the thermal gases of Bourbon-Lancy, Maizières and Santenay, which contain respectively 2, 6 and 10 per cent helium.

Special Steels. The steel used in the construction of aeronautic machinery has to have special properties

which can be realized only by the help of chemistry and metallurgy. Among the special steels found is that of Colonel Grard, a self-hardening nickel-chrome steel of the composition of C 0.25-0.40, Mn 0.40-0.60, Si 0.20-0.30, Ni 3.5-5.00, Cr 1.2-2.00. He describes briefly the properties of this special steel as well as those of nickel steel, chrome steel, tungsten steel, silicon steel, manganese-siliceous steel and chrome-tungsten steel.

Aluminum and Its Alloys. France has the advantage of possessing bauxite mines located near hydro-electric plants so that aluminum can be produced practically cheaper than anywhere else. During the war the growth of the use of aluminum has been very marked. A number of aluminum alloys have been used to advantage to replace steel in the manufacture of different parts of machinery. The alloy most used was duralumin of the composition Al 93.9, Cu 3.70, Mn 0.61, Zn 0.25, Mg 0.43, Si 0.58, Fe 0.53.

Motor Fuels. Motor fuels presented many difficult problems, especially when it is considered that the quality of the fuel is of prime importance in the efficient working of the motors. The fuels used were grouped into two classes—namely, Asiatic and American. He describes their characteristics and the care taken to free them of sulphur compounds, acids and water and to lower the proportion of unsaturated hydrocarbons.

Lubricating Oils. Special lubricating oils being required for the motors, extensive chemical studies were made to obtain oils that maintain their lubricating properties even when submitted to the very great variations in temperature encountered in aëronautics. He mentions that shortly before the war Prof. Hemptine of Liège obtained lubricating oils of very high viscosity, called polymerols, by circulating slowly a mixture of a mineral oil with a semi-drying oil between the armatures of a high-tension condenser. This product was used advantageously to increase the viscosity of fluid mineral oils. During the war the Germans confiscated the plant and worked this process for their needs.

Non-Freezing Liquids for Cooling the Motors. The usual method of making the cooling water non-freezing by the addition of alcohol or glycerine was rendered difficult by the lack of these last products. Chemical work on this problem resulted in the adoption of sodium formate as proposed by Messrs. Simon and Darmois. The addition of 270 g. per liter lowers the freezing point to below -20°C . and the solution does not attack the metals used in the radiators. Calcium chloride, a waste byproduct of the Solvay soda process, can replace advantageously the sodium formate.

Dopes. Extensive work was done to manufacture dopes appropriate to the needs of the aëronautic industry. Practically all the dopes used by the French were of cellulose acetate base; the Allies made partial use of dopes with nitrocellulose as base. Tests proved that cellulose dopes are far better than glue, gelatine, albumin, casein, bakelite, algin, alkaline glycosilicates and similar products. He passes in review the manufacture of cellulose acetate and outlines the work done to determine the appropriate mixtures used as solvents. For camouflaging dopes triacetin mixed with eugenol was utilized. Different colors were obtained by direct incorporation into the ordinary dopes of a mixture of aluminum powder, colored lakes and mineral matter.

Varnishes. Cellulose acetate being hygroscopic, the dried doped fabrics have to be varnished to protect them against atmospheric humidity. The two groups of

varnishes used were nitrocellulose varnishes and fat varnishes. Varnishes with synthetic resins as base have been developed but not used industrially. Inert or organic coloring matter was incorporated in the varnishes used for camouflaging.

Fabrics for Balloons. The material used in France was cotton fabric (seldom of silk) covered with rubber, generally two layers of cotton fabric alternating with rubber layers. Vulcanizing was done with sulphur chloride at 35°C . The problem of the influence of light on the fabrics had to be solved. The best solution found was the use in France of a lead chromate dye; Italy and Great Britain used dopes in which aluminum powder was incorporated. Tests were made to use rubber substitutes and by the end of the war France was experimenting with cotton fabrics treated with dopes having cellulose acetate as base. Even now the problem of a good material for balloons has not been solved. This problem deserves to be still further studied, especially when it is considered that helium, which is bound to become of general use for filling balloons, is too expensive a product to be wasted through the use of fabrics which are not sufficiently impermeable.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Synthetic Anthraquinone Derivative.—Anthraquinone derivatives such as alizarine may be made from phthalic anhydride by first preparing p-chlorbenzoyl-o-benzoic acid, and condensing this with concentrated sulphuric acid to form chloranthraquinone, from which alizarine may be made by treatment with caustic alkali in the presence of an oxidizing agent. JOHN M. WEISS of New York, GEORGE C. BAILEY of Woodcliff-on-Hudson, and RALPH S. POTTER of Grantwood, N. J., suggest the following method for making the chlorbenzoyl benzoic acid: A mixture of 100 parts of finely ground phthalic anhydride with 180 parts of coarse freshly sublimed aluminum chloride is added to 1,000 parts of chlorbenzene at 120°C . After a short time the temperature is reduced and water or ice is added prior to the introduction of 80 to 90 parts of 60 per cent H_2SO_4 . Excess chlorbenzene may now be removed by steam distillation. Crude chlorbenzoyl benzoic acid is filtered from the cooled mass, dried and washed. The addition of the proper amount of H_2SO_4 to the filtrate will give (upon concentration) about 230 parts of aluminum sulphate as a byproduct. (1,255,100; assigned to The Barrett Co.; Oct. 5, 1920.)

Zinc Oxide and Hydrogen.—By vaporizing carbon-free metallic zinc in a suitable retort and treating the zinc in the vapor phase with an excess of superheated steam RALPH H. MCKEE of New York is able to produce zinc oxide free from blue-powder, with hydrogen as a byproduct, according to the reaction:

The zinc oxide is recovered by cooling the reaction

product and filtering through bags. The steam:hydrogen mixture is then further cooled to condense the steam, leaving the hydrogen in a substantially pure state. (1,355,904; Oct. 19, 1920.)

Alloy for Chemical Apparatus.—An alloy of iron, molybdenum and chromium low in carbon and silicon is especially adapted to the manufacture of chemical apparatus, being sufficiently strong to resist accidental breakage and soft enough to permit being machined to shape. Iron may be replaced by cobalt or nickel; molybdenum by tungsten. Indeed, the very best alloy from the chemical standpoint is composed of nickel and tungsten, each of which is the most resistant chemically of the members of their respective groups, combined with enough chromium to constitute a mutual solvent, but the composition is comparatively expensive and somewhat more difficult to machine. Certain typical formulas are as follows, the proportions being by weight:

	A	B	C	D
Chromium.....	60	55	60	40-60
Iron group metal.....	20	25	30	10-40
Molybdenum-like metal.....	20	20	10	10-20
Carbon.....	Less than 1 per cent			
Silicon.....	Less than 1 per cent			

Column A gives the alloy that appears to be the most resistant chemically of any investigated. Columns B and C give the compositions which are most easily made when the iron group metal employed is iron. Column D indicates the limits of favorable composition. (1,357,550; FRANK A. FAHRENWALD, of Cleveland, Ohio; Nov. 2, 1920.)

Dicyandiamide as Stabilizer for Nitrocellulose.—The lower nitrates of cellulose, particularly pyroxylin soluble in ether-alcohol, may be stabilized by the addition of 0.1 to 2 per cent of dicyandiamide, $\text{NH}:\text{C}(\text{NH}_2)\text{NH}:\text{CN}$. (1,358,653; CHARLES L. REESE, of Wilmington, Del., assignor, by mesne assignments, to the Arlington Co.; Nov. 9, 1920.)

Coking Process and Apparatus.—The Wallace oil-shale retort, which has been described in *CHEM. & MET. ENG.*, vol. 22, p. 809, April 28, 1920, may be used for the distillation of coal provided certain modifications are introduced. This retort is a vertical cylinder externally heated and provided with a central perforated eduction pipe through which the vapors are removed by suction. In treating coal, coke formation proceeds in vertical concentric rings from the wall toward the center. The passage of gases or vapors through the newly formed coke must be prevented, since this causes minute cracks which develop into fissures during the final shrinkage of the coke. Two methods for overcoming this difficulty are described. (1,358,663 and 1,358,664; GEORGE W. WALLACE, of East St. Louis, Ill.; Nov. 9, 1920.)

Diaphragm for Electrolytic Cells.—Mineral wool is mixed with paraffine oil as a binder and compressed to form an osmotic diaphragm—that is, one which not only allows the free passage of ions liberated during electrolysis but also permits the diffusion of liquids by osmosis. According to MILO W. KREJCI, of Chicago, and GUNNARD E. JOHNSON, of Hammond, Ind., such a diaphragm is particularly adapted for use in the electrolytic manufacture of white lead by the Harrington process (U. S. P. 1,308,948; July 8, 1919). In this process it is essential that CO_2 ions should pass from the catholyte to the anolyte at the same rate at which lead acetate

is formed in the anode compartment, so that the precipitate of white lead may be formed in the solution away from the anode and thus settle to the bottom without any danger of coating the anode. (1,358,858; Nov. 16, 1920.)

Chlorination Process.—Saturated hydrocarbons such as petroleum naphtha are treated counter-currently with chlorine in the absence of light, yielding a solution of chlorine in the hydrocarbon mixture, which is then passed through heated coils in which chlorination takes place. After cooling, the liquid is recirculated through the chlorine absorption tower and this cycle is repeated until the desired degree of chlorination is reached. Vapors which escape during chlorination are treated in condensers and absorption towers for the recovery of valuable constituents. (1,358,851; ARTHUR E. HOULEHAN, of Wilmington, Del., assignor to E. I. du Pont de Nemours & Co.; Nov. 16, 1920.)

Acetyl Chloride and Phosphorus Oxychloride.—Glacial acetic acid is mixed with phosphorus trichloride and the temperature maintained at about 10 deg. C. while sufficient cold, dry chlorine is introduced to complete the reaction:

The reaction products are easily separated by fractional distillation since acetyl chloride boils at about 51 deg. C. and phosphorus oxychloride at 106.5 deg. C. The still residue consists largely of phosphoric acid. (1,359,071; FREDERICK J. KAUFMANN, of Charleston, W. Va.; Nov. 16, 1920.)

Chloroform From Isopropyl Alcohol.—Isopropyl alcohol gives good yields of chloroform when distilled in the usual manner with chloride of lime and water. The isopropyl alcohol may be obtained by absorbing vapors rich in propylene in sulphuric acid, followed by hydrolysis of the propyl hydrogen sulphate to give isopropyl alcohol (see *CHEM. & MET. ENG.*, vol. 23, p. 1230; Dec. 22, 1920). (1,359,099; MAX PHILLIPS, of Evansville, Wis.; filed under the act of March 3, 1883; Nov. 16, 1920.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Treating Vegetable Fibers.—Vegetable fibers of all kinds and in any stage of manufacture are treated by fixing thereon the products of the hydrolysis of proteic substance to impart to the fibers the character of wool, both physically as to feel, appearance and calorific qualities, and chemically as regards their affinity and absorbent capacities for dyestuffs. The treatment of the fibers is also a preparation for the usual printing processes. The fibers, whether in the mass or in the state of lap, cops, card-ends, twistings, yarns or fabrics, are treated with the liquid obtained by the action of strong acids, alkalis or other hydrolyzing agents on proteic substances to which oxidizing agents may be added, and are then washed with water with, if desired, a preliminary washing with a dilute acid or alkali, or a saline solution. The fibers may finally be treated with formaldehyde, alone or with ammonia, or with phosphoric acid. In a modification of the process, the fibers are impregnated with a proteic solution, the deposit being treated, if desired, with formaldehyde and tannin. The fibers may then be dried and are subsequently treated with a hydrolyzing agent, with or without the addition of an oxidizing agent, and are finally washed with water, after the preliminary washing if desired. Casein, egg

albumin, serum albumen and gelatine are mentioned as suitable proteic substances, and nitric, sulphuric, hydrochloric, phosphoric and formic acids, zinc chloride and caustic soda are given as examples of suitable hydrolyzing agents. (Br. Pat. 150,665, not yet accepted; SOC. GILLET ET FILS, Lyon, France, Nov. 24, 1920.)

Pulverizing Metals.—Zinc or other metal is reduced to powder by heating the metal to the highest possible temperature it can attain without volatilization, and pouring it in a thin stream upon a steam jet issuing at high pressure in a horizontal direction from an orifice, elongated horizontally so as to give a flattened formation to the jet. A convenient form of apparatus comprises a small furnace with a melting pot for heating the metal and a chamber, inclosed except for a space in the top, beneath which an inch steam pipe, flattened at the end to an opening, $\frac{1}{8}$ in. deep, enters, and long enough to allow the jet to expand itself in traveling its length. The molten metal poured by a ladle on to the jet a short distance from the orifice is instantly disintegrated and blown along the chamber, and may subsequently be collected, dried and screened. (Br. Pat. 150,490—1919; J. P. MILLER, Uplands, Swansea, Nov. 17, 1920.)

Granular Calcium Cyanamide.—Granular calcium cyanamide is produced by treating calcium cyanamide with more than enough water to slake the lime, etc., under such conditions of temperature and pressure that the excess water is immediately evaporated. Temperatures of 70 to 80 deg. C. and a reduced pressure are mentioned. The water may contain dissolved or suspended matter which may enter into reaction with the calcium oxide or may have a binding effect. The substances mentioned are sodium sulphate, ferrous sulphate, clay, cyanamide and potato meal, and urea. Carbonic acid may be introduced with a salt solution and may serve to spray the solution over the cyanamide. (Br. Pat. 150,979, not yet accepted; AKT. GES. FÜR STICKS-TOFFDÜNGER, Knapsack, near Cologne, Nov. 24, 1920.)

Sulphuretted Dyes.—Sulphuretted dyes, which are probably thiazines, are obtained by sulphurizing β -oxynaphthoquinonearylamides ($O:OH:NR = 1:2:4$); suitable sulphurizing agents are sulphur, alone or in presence of catalysts, solvents or diluents, disulphurdichloride, sulphur sesquioxide or alkali polysulphides, preferably in alcoholic solution at temperatures not exceeding 150 deg. C. The resulting products, if they contain sulphonic or carboxylic acid groups, are acid mordant dyes, or if they are free from such groups are vat dyes; the vat dyeings may be aftertreated with metal salts, preferably chromium salts, giving fast green to black shades. According to examples: (1) The condensation product from *p*-chloraniline and 1:2-naphthoquinone-4-sulphonic acid is heated with sulphur, naphthalene and sulphur iodide or iodine, and the product is worked up by removing the naphthalene by solvent naphtha and free sulphur by sodium sulphide solution, then dissolving the dye in concentrated sulphuric acid, pouring on ice, filtering and washing; the paste gives a yellow hydrosulphite vat dyeing wool violet-black shades which turn to claret-red on treatment with acid, and bluish-green on treatment with chromium salts in acid solution; similar dyes are obtained by the above treatment from the condensation products of 1:2-naphthoquinone-4-sulphonic acid with aniline, *o*-, *m*- or *p*-toluidine, *p*-anisidine, or *p*-phenetidine; (2) the condensation product from 1:2-naphthoquinone-4-sulphonic acid

and *p*-anisidine is treated at ordinary temperature with disulphurdichloride and acetic acid; the product dyes wool in a vat violet shades becoming green on after-treatment with sodium bichromate in an acid bath; similar products are obtained by the action of disulphurdichloride on the condensation products of 1:2-naphthoquinone-4-sulphonic acid with *m*- or *p*-toluidine; (3) the condensation product from *p*-toluidine and 1:2-naphthoquinone-4-sulphonic acid is treated with a solution of sulphur in fuming sulphuric acid; the product is a sulphonic acid dyeing wool from an acid bath green shades with chrome mordants; similar green to greenish-black acid mordant dyes are obtained from the condensation products of aminosalicic acid or aminocresotinic acid with 1:2-naphthoquinone-4-sulphonic acid by treatment with disulphurdichloride or sulphur sesquioxide, and a black acid mordant dye by treating with sulphur sesquioxide the condensation product from *p*-nitraniline and 1:2-naphthoquinone-4:6-disulphonic acid; (4) the condensation product from amino-N-ethylcarbazole and 1:2-naphthoquinone-4-sulphonic acid is boiled with alcoholic sodium polysulphide; the product gives a yellow hydrosulphite vat dyeing wool or cotton green shades which may be afterchromed. (Br. Pat. 151,000, not yet accepted; L. CASSELLA & Co., Frankfurt-on-Main, Germany, Nov. 24, 1920.)

Rubber Sponges.—Rubber sponges are formed so as to have large and small pores in different parts of the sponge, either by vulcanizing together superposed layers of two different compounds which will yield on vulcanization portions having large and small pores, or layers of the same compound one part of which has been masticated more than the other and forms larger pores on vulcanization. Alternatively, a mixture of the two compounds is vulcanized while supported in a shallow vessel of water with its lower part dipping into or just above the water. A compound which yields on vulcanization small pores consists of para rubber, milk of sulphur, lithopone, crimson sulphide of antimony or vermilion, ceresin wax, pine oil, together with ammonium carbonate or amyl acetate. In a compound for yielding large pores, larger proportions of carbonate or amyl acetate are used, precipitated chalk and zinc oxide are used in place of lithopone and turpentine may partially replace pine oil. (Br. Pat. 151,084. G. W. BELDAM, London, and A. U. B. RYALL, Brentford, Middlesex; Dec. 1, 1920.)

Cyanides.—In the production of cyanides by the reaction of free nitrogen or a mixture of an alkali or alkaline-earth metal or compound, carbon and a catalyst, the catalyst, such as iron manganese, nickel or copper, is introduced in the form of a compound not containing any element other than carbon, hydrogen, oxygen and nitrogen, and is reduced at a temperature below 550 deg. C. Iron hydroxide prepared by precipitating ferrous sulphate with ammonia, and iron oxalate are mentioned. (Br. Pat. 151,098. C. T. THORSSELL and H. L. R. LUNDEN, Gothenburg, Sweden; Dec. 1, 1920.)

Retting Flax.—In obtaining fibers from flax, the straw, prior to retting, is treated in one stage, or in a number of stages extending over successively increasing periods of time, with an alkaline solvent to remove the whole or a greater portion of the gum and resin compounds, and the retting operation is carried out in an alkaline medium. A natural soda, such as Magadi soda, occurring in East Africa, may be used, and in the

retting operation, which is preferably effected at 80 to 95 deg. F., the liquid is continuously aerated and circulated. (Br. Pat. 151,143. L. A. JOHNSON, Uasin Gishu, East Africa Protectorate; Dec. 1, 1920.)

Alumina; Basic Aluminum Nitrate.—A solution of aluminum nitrate is evaporated to distil off dilute nitric acid, and water, steam or fresh solution is added so as to keep the temperature constant (about 140 deg. C.) until the bulk of the alumina is precipitated as a crystalline basic nitrate which is practically free from iron even if the solution is ferruginous. It is advantageous to treat solutions containing calcium or sodium nitrate, which remains in solution in the mother liquor. Such solutions may be obtained by adding some base or salt such as limestone to the nitrate solution before heating. Alternatively the solution of nitrate to which such a base or salt has been added or from which some acid has been distilled off may be heated under pressure in an autoclave to effect the precipitation of the basic nitrate. The basic nitrate obtained as above described is heated to obtain alumina and nitrogen oxides which are converted into nitric acid. The mother liquor is treated with nitric acid to convert the alumina content to normal nitrate and the solution is evaporated until aluminum nitrate crystallizes out and may be returned to the original solution and the remaining mother liquor is evaporated to dryness to recover the sodium or calcium nitrate. (Br. Pat. 151,259, not yet accepted. NORSKE AKTIESELSKAB FOR ELEKTRO KEMISK INDUSTRI, Christiania; Dec. 1, 1920.)

Automatic Detector for Arsenic in Gases.—In apparatus for regulating production, a sample of the initial material is withdrawn and is passed to the testing apparatus which acts in such a manner that the presence of an undesirable substance in the sample causes a variation in the quantity or character of radiant energy

ARSENIC DETECTOR

such as light projected through the apparatus, and the variation so produced is utilized to operate means controlling the process of production. The invention is described with reference to the manufacture of sulphuric acid by the contact method, the control depending on the presence of arsenic in the reaction gases. Thus, a sample of the gases is passed to an electrolytic Marsh apparatus 5, the gases from which, after purification in a tube 9, are burned at the jet 11, the flame impinging on a quartz glass or like transparent screen 12 arranged between a source of light 16 and a light-sensitive cell 15; if arsenic is present, a mirror is formed on the screen 12 and serves to cut off more or less the light falling on the cell 15. The latter is in circuit with a relay 32, and the increase in resistance in

the cell 15 consequent on the cutting off of the light actuates the relay to close a circuit 29 and to energize a solenoid 28 controlling through a valve 26 the supply of fluid under pressure in the pipe 25; opening of the valve 26 actuates a piston 23, which in turn operates the main three-way valve 14, so that if arsenic is present in the gases these are bypassed back to the purifying apparatus 3. The screen 12 is periodically cleaned by a wiper 34, and if the impurity is no longer present, the relay 32 comes into action to open the circuit 29 and to de-energize the solenoid 28, and the valve 14 then returns to its original position to pass the gases to the contact apparatus 1. In other instances—for example, in the case of liquids—the control may be based on the extent to which the plane of polarization of light is rotated, or on variations in the refractive index, or it may depend on the fact that the objectionable constituent yields a colored product on treatment with a chemical indicator, in which case a source of light of the complementary color would be employed. (Br. Pat. 151,328; L. LOGAN, Arlington, Mass., Dec. 8, 1920.)

Cyanamide.—Cyanamide practically free from dicyandiamide is obtained in solution by supplying successive quantities of calcium cyanamide to water or a cyanamide solution while supplying enough carbon dioxide to maintain the solution neutral or only slightly alkaline. By starting with a cyanamide solution very strong solutions can be obtained. The reaction is effected at a temperature not above 70 deg. C., and the carbon dioxide is preferably supplied under pressure, being blown into the solution by nozzles; or other means of bringing the gas into intimate contact with the liquid may be employed, such as beaters; or the solution containing calcium cyanamide may be sprayed into an atmosphere of carbon dioxide. The carbon dioxide may be pure or mixed with other gases, as, for instance, combustion or lime kiln. (Br. Pat. 151,583, not yet accepted; WARGONS AKTIEBOLAG and J. H. LIDHOLM, Wargon, Sweden; Dec. 8, 1920.)

Alkali Silicates.—In order to obtain a soluble alkali silicate of high silica content, the product obtained by the fusion of alkali and silica is dissolved in water and an acid then added, whereby gelatinous silicic acid is thrown down, and this precipitate by continued agitation is made to re-dissolve in the solution. The acid, preferably sulphuric acid, may be added in the form of spray; and after the subsequent operation of agitation or grinding, the solution may be evaporated to dryness. Moreover, to increase the fusibility of the alkali and silica, a little borax may be employed in the fusion process. (Br. Pat. 151,339. F. J. PHILLIPS, London, and E. J. ROSE, Therwood; Dec. 8, 1920.)

Calcium Phosphate.—Natural tricalcic phosphates are mechanically treated to obtain two fractions, one of rich granules containing a high percentage of phosphate, and the other of a mixture containing calcium carbonate and phosphate in so fine a state of division as to be assimilable by the roots of plants. The nodules of natural phosphate are first broken down and then treated in a rotary disintegrator through which a blast of air is directed. By this means the granules of phosphate are freed from the carbonate dust which covers them and the mixture is carried away to chambers where the two fractions separate out according to density. (Br. Pat. 151,684. W. P. THOMPSON, Liverpool, Compagnie des Phosphates de Constantine, Paris; Dec. 8, 1920.)

in the Chemical and Metallurgical Industries

Patent Office Bill Hearings This Week

Hearings on the Patent Office bill, with its rider authorizing the Federal Trade Commission to administer Government patents, will begin Jan. 5. The hearing is before the conference committee of the two houses of Congress. The Patent Office bill proper has passed each house. The rider was attached by the Senate.

Representatives of chemical industries are to be heard as to the possible effects of extending a reward to Government employees for such inventions as they may develop. Some are afraid that the effect of this reward will be detrimental to the outside inventors, in that the Government employee could pursue his inventive work while on the Government payroll and with the Government's facilities. It is argued that the tendency among Government employees would be to neglect the regular research work and concentrate on a device or a method which promised personal pecuniary reward. The conference committee expects to hear each side of the case before taking action on the bill.

Progress of American Engineering Council

The Executive Board of American Engineering Council met in New York on Dec. 17, with all members present excepting A. M. Greene. Two new members of the Board were elected, W. B. Powell, Buffalo Engineering Society, representing District 1, New York and New England States, and Gardner S. Williams, Grand Rapids Engineering Society, representing District 2, Michigan, Wisconsin and Minnesota.

President Hoover appointed the following standing committees:

Procedure.—Calvert Townley, chairman; Herbert Hoover, ex officio; W. E. Rolfe, D. S. Kimball, J. Parke Channing, L. W. Wallace, L. P. Alford.

Constitution and Bylaws.—W. B. Powell, chairman; C. F. Scott, D. S. Kimball.

Publicity and Publications.—L. P. Alford, chairman; H. W. Buck, H. E. Howe.

Membership and Representation.—J. F. Oberlin, chairman; L. W. Wallace, A. S. Dwight.

Finance.—William McClellan, chairman; E. Ludlow, C. Townley, L. W. Wallace, ex officio.

Public Affairs.—J. Parke Channing, chairman; Fred J. Miller, L. B. Stillwell.

In discussing the immediate program of Council, Mr. Hoover announced that he had called together engineers in various cities and found that while they were favorably disposed toward the Federation, there was a strong trend toward territorial as distinguished from national organization. One of the obstacles to uniting territorial organizations in the Federation is the question of dues. Another complication is the membership of numerous individuals in more than one society. Deeming the question of territorial organization of vital importance, Mr. Hoover suggested the appointment of a committee to canvass the situation carefully. After considerable discussion the matter was referred to a special committee which will include the six district delegates.

Necessary action was taken to make it possible for certain activities of Engineering Council to be taken over by the new organization as soon as the United Engineering Societies has passed officially on the proposed transfer. In this event President Hoover will appoint the necessary committee of American Engineering Council to take over and continue the uncompleted work of Engineering Council's committees.

Action was taken to amend section 9, paragraph 6, of the bylaws so that committee members can be selected from societies other than those now belonging to the Federation, thus making it possible for civil engineers and others not now affiliated with the Federation to co-operate in committee work.

Council voted not to affiliate with the United States Chamber of Commerce. It also appropriated \$1,000 as an initial fund for publicity work, and authorized the committee on publicity and publications to establish a board of engineering editors. It was voted to pay the expenses of members of the Executive Board for attendance at meetings. A special committee reported on candidates for executive secretary of the organization, but no action was taken. The place of the next meeting, which will be held Feb. 11, was left to the discretion of the president.

Patents Obtained by Department of Agriculture Employees During 1920

During the last fiscal year thirty-five patents were allowed for inventions by employees of the United States Department of Agriculture the benefits of which are dedicated to public use. Thirty applications for patents were prepared by the department's office of the Solicitor during the year, some of which were pending at the close of the fiscal period.

The patents allowed cover a wide scope and some of them are believed by the department to be highly valuable to the public. The list of those allowed during the year includes cane stripping comb, manufacture of cymene sulphonic acid, synthetic ammonia (2), photographic sensitizing dyes (2), new insecticide, production of ammonia, curing tobacco, atmometer, phosphorus and phosphorus acid, dextrine, process for removal of hydrofluoric acid from phosphoric acid, bleaching wood, improvement in the synthetic manufacture of thymol, vanillyl amine, vanillyl acyl amides and production thereof, and fruit grader and sizer.

Applications for patents on the following inventions were pending at the close of the year: Method of manufacturing decolorizing carbon, process for the manufacture of naphthalene sulphonic acids, tree trimming and harvesting machines, panoramic camera attachment, process of sublimation, adhesive, apparatus for controlling reactions between gases (2), ammonium nitrate, insecticide and fungicide, grain samplers, malt sirup (2), process of extracting soluble albumen from whey, manufacture of furfural and volatile organic acids from corncobs, manufacture of furfural and volatile organic acids from corncob pentosan, preserving

apples, grain sampler, apparatus for sterilizing fruit juices, new and improved types of bread, manufacture of sweet potato sirup, new process for preparing sirup from sugar beets, protosensitizing dyes of the isocyanine type, gelatine or glue free from mineral matter, acids, or alkalis, and a process for preparing same.

The Government and the people of the United States are entitled to make use and sell the inventions disclosed by these patents freely and without the payment of royalty to the patentees.

No Appropriation for Chemical Industries

The Committee on Appropriations of the House of Representatives used the knife relentlessly on the requests made by the Bureau of Mines for funds for its work during the next fiscal year. The \$125,000 asked for non-metallic and chemical industries research went out altogether, as did the \$30,000 for low-temperature research and the \$29,920 requested for aluminum research. For the most part, the committee allowed no increases over the appropriations for the current fiscal year. The only new item in the bill, as reported on Dec. 29, was \$50,000 for enforcing the oil land-leasing regulations. The bureau had requested \$132,390 for that work. The total appropriation carried by the bill for the Bureau of Mines was \$1,357,300.

In addition to the carefully written justifications prepared in support of these estimates, Dr. F. G. Cottrell, the director of the bureau, argued in person before the Committee on Appropriations.

In support of the aluminum research, Dr. Cottrell pointed out to the committee the possibility of obtaining aluminum production from sources and ores not now being utilized. He also emphasized the need for better and cheaper methods of aluminum production.

The failure of the committee to allow \$30,000 for low-temperature research is regarded as particularly lamentable, since the entire installation for that work has been turned over to the Bureau of Mines, without expense, by the War Department.

The War Department purchased complete equipment for the cryogenic laboratory, which was set up by the Bureau of Mines in its own offices. The co-operative agreement provided that the laboratory was to become the property of the Bureau of Mines after the War Department work had been completed.

The committee allowed \$200,000 for the operation of the mining experimenting stations. This is the amount of the current appropriation. The bureau has requested \$270,000 for its work in this direction during the next fiscal year.

Important Legislation on the Tapis

The first week of the new year saw many chemists journeying to Washington. Three important matters of particular interest to the chemical industries have come up for active consideration on the part of Congress. The chemical schedule of the new tariff bill will be considered at the first of the series of hearings to be held by the Committee on Ways and Means. The Patent Office bill, with its rider authorizing the Federal Trade Commission to administer patents granted to Government employees, comes up for hearings beginning Jan. 5. The third matter is the bill authorizing the creation of the United States Fixed Nitrogen Corporation.

Since so many chemical activities come within the infant industry class, the need for a protective tariff is

felt by a large number of the subdivisions of the industry. As a result these hearings are expected to be of unusual interest.

In view of the apparent determination of some of the members of the conference committee on the Patent Office bill to force it through, rider and all, the hearings before that body seem to be the only hope that the opponents of the rider have to secure the defeat of the legislation.

There is increasing hostility to the Fixed Nitrogen Corporation bill, especially in view of the changed economic situation. The manufacture of fertilizer materials on a large scale at this time by the Government is denounced very strongly in some quarters. Efforts are being made to stir up opposition to the measure in the Senate. A very little opposition aroused now, with the end of the short session in sight and with unprecedented congestion of the legislative program, would be all that is necessary to prevent passage of the bill. Should the effort in the Senate fail, there is a good chance to block it in the House, it is believed, owing to the disinclination to authorize any further appropriations. The present situation in the nitrate market is such that it is not believed to be feasible to finance the corporation from funds which might be obtained from the sale of the War Department's reserve of sodium nitrate.

British Dye Bill

The text of the British dye bill, which passed the House of Commons Dec. 20, is as follows:

With a view to the safeguarding of the dye-making industry, the importation into the United Kingdom of the following goods—that is to say, all synthetic organic dyestuffs, colors and coloring matters, and all organic intermediate products used in the manufacture of any such dyestuffs, colors or coloring matters—shall be prohibited.

Goods prohibited to be imported by virtue of this act shall be deemed to be included among the goods enumerated and described in the table of prohibitions and restrictions inwards contained in section 47 of the customs consolidation act, 1876, and the provisions of that act and any act amending or extending that act shall apply accordingly.

The Board of Trade have power by license to authorize, either generally or in particular case, the importation of any of the goods or any class or description of the goods prohibited to be imported by virtue of this act.

For the purpose of advising them with respect to the granting of licenses the Board of Trade shall constitute a committee consisting of five persons concerned in the trades in which goods of the class prohibited to be imported by this act are used, three persons concerned in the manufacture of such goods, and three other persons not directly concerned as aforesaid. Such one of the last-mentioned three persons as the board shall appoint shall be chairman of the committee.

For the purpose of providing for the expenses incurred by the board in carrying this act into execution, the board may charge in respect of a license a fee not exceeding £5.

Subject to compliance with such conditions as to security for the re-exportation of the goods as the Commissioners of Customs and Excise may impose, this act shall not apply to goods imported for exportation after transit through the United Kingdom or by way of transshipment.

Anything authorized under this act to be done by the Board of Trade may be done by the president or a secretary or assistant secretary of the board or by any person authorized in that behalf by the president of the board.

The provisions of this act shall continue in force for a period of ten years from the commencement thereof and no longer.

This act may be cited as the dyestuffs (import regulation) act, 1920.

Bill for Federal Manufacture of Atmospheric Nitrogen Expected to Pass the Senate

The bill providing for federal manufacture of atmospheric nitrogen is expected to pass the Senate, but strong opposition to the measure has developed in the House, where its course is likely to be more difficult. Senator Underwood of Alabama, the minority leader, has given notice that the minority will employ such methods as are available to insure its passage.

The opposition in the House is based for the most part on the probability that the enterprise will call eventually for large appropriations. The bill provides for the financing of the proposed United States Fixed Nitrogen Corporation by the sale of a portion of the War Department's reserve of nitrate of soda. Now that the price of nitrate has declined materially since the bill was drafted, it is feared that it would not be wise to attempt to raise the \$12,500,000, for which the bill calls, from the sale of the nitrate reserve, since at present prices it would deplete that reserve unduly.

Book Reviews

PLANTATION RUBBER AND THE TESTING OF RUBBER. By G. Stafford Whitby. 555 pages. New York: Longmans, Green & Co., 1920. Price \$9.50 net.

Although there have been extremely few contributions to the technology of rubber goods manufacture, the literature on crude rubber is rather abundant. This is due in a great measure to the fact that both the Dutch and the British went into the systematic planting of rubber trees before the beginning of this century.

The author of this work has divided his book into two almost equal parts. The first part treats of such topics as methods for obtaining the milk from the rubber trees, collection of this latex, coagulation of the latex, conversion of the coagulated milk into sheets, and the process of "smoking" sheet rubber. In Part II of his book the author has presented many data on rubber from the viewpoint of the physical chemist. He has discussed such subjects as Young's modulus, Hooke's law, the stress-strain curve for rubber, and tensile tests. In his discussion of tensile strength and elongation the author passes over the Henry Scott testing machine with a two-line note, which is disappointing for American readers. The literature references are for the most part English and Dutch, although one finds casual references to the work of Kratz, Flower, Tuttle and Cranor in the United States.

Although the rubber industry was born the day Good-year discovered vulcanization in 1839, it was not until about 1910 that serious scientific work was done in the field of rubber chemistry. Even the theory of vulcanization was not proposed before Carl Otto Weber in 1902 published his now historic book. The rubber industry was in fact a "house of mystery" until the demands made by consumers of rubber goods compelled the manufacturers to invite chemists into their plants. And so it comes that we find in the present text books such phrases as "co-efficient of vulcanization," "accelerated aging tests," "optimum cure" and "state of cure."

Forty-four pages have been devoted to a bibliography in which the author has discovered 350 names of writers on rubber topics in book and periodical literature. Unfortunately he has omitted all mention of the valuable papers which have appeared in *CHEMICAL & METALLURGICAL ENGINEERING* during the past five years. All reference to synthetic rubber has been carefully deleted from the book, as well as from the bibliography, but a considerable number of unimportant publications have been noted. In spite of this the author has rendered a service of unusual value to

rubber investigators who desire to find references on plantation rubber and rubber testing.

In general the short-sentence style has been used, but sentences of 120 words (page 261) should be modified in later editions. Aside from this the text is readable, the subject matter true, the proof carefully corrected, and a great deal of material on the physics and physical chemistry of rubber has been published in book form for the first time. In this country the book will probably be of greater value to university men than to manufacturers of rubber goods.

FREDERIC DANNERTH.

Obituary

Dr. HENRY A. BUMSTEAD, professor of physics at Yale University, who had been on leave of absence serving as chairman of the National Research Council, died on a train en route from Chicago to Washington on Dec. 31. He had just taken a very active part in the Christmas week meetings of the various scientific societies. The death of Dr. Bumstead comes as a shock to the scientists of the country and particularly to the National Research Council, where he was in the midst of a constructive program for the work of that institution. The services rendered by Dr. Bumstead during the war were particularly notable. As an attaché of the American Embassy at London he was in immediate charge of the exchange of confidential scientific data with the Allies. Due to his twenty-seven years of service as an instructor at Yale, Dr. Bumstead has influenced the thought of many thousands of students. As a result of his particularly attractive personality, these students have clung to him with unusual affection. The laboratory at Yale which was under his direction is regarded as one of the finest in the world. Dr. Charles Walcott, the vice-chairman of the National Research Council, will succeed Dr. Bumstead at least temporarily as the active chairman of the Council. Dr. Bumstead was fifty years old and was graduated from Johns Hopkins University in 1891, later receiving his doctor's degree from Yale.

Personal

RICHARD H. CATLETT has resigned his position as production manager of the Taylor Chemical Co., Penn Yan, N. Y., and is now chemical engineer with the Lewis Recovery Corp., Boston, Mass.

CHARLES A. EDWARDS, for many years manager of the Portland, Ore., office of A. O. Anderson & Co., has severed that connection to become head of the Portland Vegetable Oil Milling Co., Portland.

Dr. SAMUEL EYDE, joint inventor of the Birkeland-Eyde arc process for nitrogen fixation, arrived in New York on Dec. 30. He plans to make an extensive visit in the Canadian nickel territory.

Dr. CARL HERING of Philadelphia, Pa., has moved his office from 210 South 13th St. to 1317 Spruce St.

Dr. J. A. MONTGOMERY, formerly chief chemist for the Structural Materials Research Laboratory, has resigned to become chief chemist for the Borromite Company of America, 105 West Monroe St., Chicago, Ill.

H. L. MOYLER resigned his position Nov. 1 as assistant superintendent of acid plants, Naval Proving Grounds, Indian Head, Md., to become general supervisor of acid production, Monsanto Chemical Works, Plant B, East St. Louis, Ill.

Dr. M. C. TEAGUE, formerly gas chemist at the Pittsburgh station of the Bureau of Mines, is now research chemist with the United States Rubber Co., 561 West 58th St., New York City.

Current Market Reports

The Chemical and Allied Industrial Markets

New York, Jan. 3, 1921.

Reflections of the holiday week were apparent in the chemical market and trading in most quarters was reported quiet. However, the tone of the general market is steady. The trade is looking forward to the new year with confidence, although it is generally conceded that business will probably be slow during the next few weeks. Opinions of the dealers and manufacturers show a feeling more hopeful for a resumption of activity. Those close to the inside workings of the market stated that sellers are plucking up more nerve and that buyers have been turned down on several occasions because they refused to meet an advance in lately prevailing prices.

The extent of business has not improved much on the surface of the market and it is not expected to improve materially until the holiday excitement and inventory periods are out of the way. There is no denying that buyers have shown more interest in the market than for several weeks and sales have been freer although of small individual volume.

Solid caustic soda displayed a firmer tendency in the open market and offerings of standard material were not much in evidence. Buying was considered good in several quarters and rumors were current of large interests operating. Spot prices ranged from \$3.75 to \$3.85 per 100 lb. for carlots. Occasional odd lots moved at a shade under this figure through brokers. Makers were still holding contract prices at 3½c. per lb., basis 60 per cent, f.o.b. works, over next year.

Producers reported quiet trading in *yellow prussiate of soda*. Large manufacturers were willing to book contracts at 18c. per lb., but stated that consumers were not taking much interest in futures. Second hands are doing business in small lots at prices ranging from 17c. to 17½c. per lb. Makers of *silicate of soda* quote \$2.90@3 per 100 lb. for the 60 deg. Bé. in large lots and up to 3½c. per lb. for small lots. Business was reported quiet, with sales mostly moderate for home and abroad. The 40 deg. test is offered at \$1.15@1.25 per 100 lb. in carload lots and up to \$1.50@1.75 in small quantities. Single bags of *soda ash* were held at \$1.90@2 per 100 lb. at the works for prompt shipment. Offerings continued limited and the market showed a steady tendency. Resale lots for export were quoted at \$1.85@1.90 with scattered transactions reported. Barrels ranged about 5c. per 100 lb. advance. Contracts continued to be quoted by producers for 1921 shipment at \$1.82½@1.90, basis 48 per cent, f.o.b. works.

Manufacturers of *sodium sulphide* are trying to keep the price of the 60-62 per cent at 7c. per lb. for drums in carload lots. Resale material was evident on the market at lower prices and sales were made down to 6c. per lb. Resale *bleaching powder* in large drums was on the market at 2½c. per lb. and it seemed possible that some interests would shade this figure on firm business. The supply could not be called heavy, but the demand gave the market an easy appearance. Producers of *glaubers salt* reported prices at 1½c. per lb. in bags. Barrels were held at \$2.05 per 100 lb. for carlots and \$2.35 in smaller quantities. Some foreign *oxalic acid* was offered on the market as low as 17½c. per lb., but most dealers gave 18½c. as the prevailing price for prime American material and prices extend all the way up to 20c. per lb. depending entirely upon brand, quantity and seller. Trading has remained quiet in this commodity, as prices are somewhat above the views of buyers.

Resale *formaldehyde* is commanding 18½c. per lb. in barrels on the spot market and business was known to have been placed at this level. Round lots are very scarce and in some quarters 19c. is the best offering for goods ex warehouse. The undertone was reported very steady. *White granular sal ammoniac* was offered on the open market at 10½@11c. per lb., with little trading reported at these low

figures. Odd lots of the gray material were available at 9½@10c.

SODIUM PRODUCTION

According to a recent report by the United States Geological Survey, the production of sodium compounds in the United States was slightly less during 1919 than it was in 1918, the total for 1919 being 9,393,749 short tons, as compared with 10,199,493 for the preceding year. The total value of these products declined from about \$143,000,000 in 1918 to slightly more than \$121,000,000 in 1919. This total includes the production of common salt, which accounts for practically 7,000,000 short tons of the total for both years. About 500,000 tons of sodium chloride was imported in 1919.

During 1919, exports of many of the sodium compounds were heavier than in 1918. The use of sodium products instead of potassium is being continued and has been materially increased because of sodium compounds being cheaper.

The following is a table of various important sodium compounds produced during 1918-1919:

	1918, Tons	1919, Tons
Acetate soda.....	2,622	2,426
Bicarbonate soda.....	118,535	134,962
Bichromate soda.....	26,526	28,334
Soda ash.....	981,054	1,390,628
Yellow prussiate soda.....	3,437	4,525
Caustic soda.....	355,466	513,363

COAL-TAR PRODUCTS

Despite the holiday recessions, offerings and inquiries were more in evidence. This showed a renewal of interest was taking the place of a long period of dullness. There were no inquiries of large enough volume to mention. Operations in some markets are beginning to show a little life and sharp-sighted merchants see that the curtailment of production and low prices have gone pretty near the limit. They also believe that stocks of many kinds have reached a level where buying now is a safer proposition.

The crude market was also a dull affair with little trading in any quarter. *Naphthalene* flakes and balls showed a firmer tendency, although trading was of a light nature. Only very small lots of *orthotoluidine* were in demand and supplies were easy, with prices ranging from 30c. to 35c. per lb. Recent trading in *paranitrophenol* has been limited to small lots on a basis of 75@80c. per lb. Producers of *beta naphthol* reported a fair volume of supplies available at 40@45c. per lb. Second hands are still offering goods and 38c. seems possible on distressed lots. *Diethylaniline* was offered in very small quantities among second hands and producers reported conditions quiet. Supplies were fairly easy at \$1.35@1.45 per lb.

VEGETABLE OILS

The market on vegetable oils remained quiet and uninteresting during the holiday week. Prices in most cases were nominal, with no large business consummated. Crushers of *linseed oil* reported that the inquiry was almost at a standstill so far as round lots were concerned. Operators were reluctant to name 78c. per gal. without any real bids to work upon. Consumers were offered raw linseed at less than 78c. for January-April shipment. Producers of No. 1 U.S.P. *castor oil* quoted the market at 12c. per lb. in barrels. The technical grade has been revised to 11½c. per lb. The outside market has sold the No. 3 type as low as 9½c. *Crude corn oil* was unsettled due to the drop in cottonseed oil, and the market closed nominal at 6½c. per lb., sellers' tanks, for immediate shipment from Chicago. No business was reported in *coconut oil* in carlots during the week. Prices held on an even basis, both here and on the Coast. Domestic Ceylon type oil held at 9c. per lb. sellers' tanks, f.o.b. Coast, with the Manila at 9½c. for January-March shipment.

The market on *palm oil* was unsettled, with lower prices in evidence in some directions for future. Lagos for shipment closed nominally at 7½c. per lb. Niger closed at 7½c. for prompt shipment from abroad. Offerings for *soya bean oil* appeared more plentiful and slightly easier prices for prompt shipment oil were noted. Inquiry was dull. Soya bean oil for December shipment from the Coast was offered at 5½c. per lb., sellers' tanks, while there were sellers of January-March at 5½c.

Chemical Market for 1920

During the latter half of 1920 the chemical industry underwent the most radical change in its history. Liquidation and all that goes with it exerted full force on the chemical market and prices yielded in almost every important item. Tight collections, efforts to ship goods prior to the advanced freight rates that became effective Aug. 26, 1920, and the influx of surplus stocks held by large consuming plants have been factors all working against the maintenance of a steady market. Reports from New England noted a state of acute quietness among most of the dye and bleaching plants. This condition was also reflected all through the textile industry. Finished textile products were not in demand and factories had to close their doors to thousands of employees. Several of these plants offered bichromate, prussiate and caustic soda for resale in the open market through various dealers. Arrivals were often considerably under the market to facilitate a quick sale.

The American export trade during the first six months of 1920, helped by Europe and Japan, established the United States as the leading chemical center of the world. Prices were reflected by the persistent demand and for several months speculators who had contracted long before were reaping the benefit of a soaring market. Spot stocks were partly wiped out and with the shortage of fuel, railroad entanglements and general existing abnormal conditions large producers were forced to shut down their plants. Germany's future after the war was another situation that kept foreign buyers on edge. When it was clearly evident that the German industry was not in a position to supply the rest of the civilized world, those who had been holding off flooded the American market with voluminous orders for miscellaneous chemicals and dyestuffs. This delicate situation brought speculation to its highest point and commodities were known to have advanced 10 to 15c. per lb. within twenty-four hours. Japanese buyers in their over-enthusiasm joined in the procession and played the speculative game harder than any of their neighbors. It was Japan that helped prices reach their highest peak and also their lowest level. Japan went into the market as a blind buyer and within a short period realized that she had bought enough for her requirements for the next three years. The surplus purchasing had a mortifying effect on Japanese financiers.

COMPARATIVE PRICES OF GENERAL CHEMICALS, JANUARY TO DECEMBER, 1920

	Jan.	June	Oct.	Nov.	Dec.
Acetic acid, 28%, lb.	\$0.02½	\$0.03½	\$0.03½	\$0.03	\$0.03
Acetic acid, glacial, lb.	.12	.16	.11½	.11½	.10½
Muriatic acid, 20 deg., 100 lb.	1.75	3.50	2.00	1.85	1.85
Nitric acid, 40 deg., lb.	.06½	.07½	.07½	.07½	.07
Oxalic acid, lb.	.33½	.58	.40	.25	.18½
Sulphuric acid, 66 deg., ton.	21.00	23.00	21.00	21.00	21.00
Acetate of lead, lb.	.12½	.13½	.14½	.14½	.13½
Ammonia alum, lump, lb.	.04	.04½	.04½	.04½	.04½
Potassium alum, lump.	.07½	.07½	.05½	.05½	.05½
Aluminum sulphate, iron free, lb.	.02½	.03	.05	.04	.03½
Aluminum sulphate, commer., lb.	.01½	.02	.04½	.03	.02½
Aqua ammonia, 26 deg., lb.	.07	.09	.09½	.07½	.06½
Sal ammoniac, white, lb.	.14½	.17½	.14	.12½	.10½
Arsenic, white, lb.	.10½	.14½	.14	.13	.11½
Barium chloride, ton.	80.00	150.00	120.00	100.00	75.00
Bleaching powder, lb.	.02½	.06½	.07½	.06	.03½
Carbon tetrachloride, lb.	.11	.11	.13½	.13	.12
Cobalt oxide, lb.	1.50	2.00	4.00	4.00	3.90
Copper sulphate, lb.	.08½	.08	.08	.07½	.06½
Cream of tartar, lb.	.55	.56	.52	.45	.38
Epsom salt, U. S. P., lb.	.02½	.04½	.04	.03½	.03
Formaldehyde, lb.	.40	.51	.40	.23	.18½
Glauber salt, lb.	.01½	.02	.02½	.02	.01½
Lead arsenate, paste, lb.	.16	.16	.16	.15	.13
Bichromate potash, lb.	.30	.42	.30	.22	.17½
Carbonate potash, 80-85%, lb.	.23	.21	.19	.15	.12
Caustic potash, 88-92%, lb.	.30	.28	.25	.17	.14
Muriate potash, ton.	150.00	115.00	105.00	100.00	100.00
Nitrate potash, lb.	.13½	.13½	.14	.11½	.11½
Permanganate potash, U. S. P., lb.	.60	.85	.70	.65	.60
Prussiate potash, yellow, lb.	.37	.36	.38	.36	.33
Acetate soda, lb.	.06½	.12	.11	.08	.06½
Soda ash, light, 100 lb.	2.00	3.25	2.50	2.00	1.85
Bichromate soda, lb.	.19	.32	.16	.11	.09½
Caustic soda, solid, 100 lb.	4.35	6.50	4.00	4.00	3.75
Chlorate soda, lb.	.12	.12	.12	.11	.10
Cyanide soda, lb.	.28	.35	.34	.26	.23
Fluoride soda, lb.	.14	.19	.21	.20	.17
Nitrate soda, lb.	.03	.03½	.03	.02½	.02½
Prussiate soda, lb.	.25	.26	.24	.19	.17½
Salsoda, 100 lb.	1.25	1.25	2.00	2.00	2.00
Sulphide soda, 60%, lb.	.05	.10½	.09	.07½	.06½
Tin oxide, lb.	.60	.65	.52	.50	.50

Credits were immediately stopped and Japan shifted from the position of leading buyer to the selling end in a vain attempt to cover her great losses. Failures among large business interests and banks followed on the heels of this change, and it was not long after that the rest of the world followed suit. Cancellations on old contracts bought by domestic dealers and foreign orders were noted. Steamers docked with cargoes of returned surplus material. All this was dumped on the American market for resale. It is in this condition that the chemical market finds itself at the turn of the year.

Perhaps the outstanding feature of the chemical market during the past year was the unique position of the dealer with his resale material and prices. During the latter part of 1919, jobbers foreshadowed a rising market and contracted heavily with manufacturers at low figures. These chemicals were later turned over at huge profits when the scarcity arose. Since June, however, prices have continually been on the decline and in some commodities the resale market has been consistently below the cost of manufacturing. Leading interests are of the opinion that the downward trend has run its course on most of the important items and that the first quarter of 1921 will be the impetus for another strong market that will once more bring out the American chemical industry as the guiding light for the rest of the world.

The Iron and Steel Market

Pittsburgh, Dec. 31, 1920.

In the past week the steel market as a whole has been even quieter than formerly, if such a thing is possible. There has been no open demand to speak of, and prices have not been tested. The view formerly held still obtains, and even more strongly, that the turn of the year will witness a mild resumption of buying. No general movement is expected for January, or even for several months to come, but it is held that complete stagnation cannot in the nature of things prevail for any length of time. The common attitude of buyers has been that they have no quarrel with the market, but simply have no interest in it. They are busy with year-end adjustments, unusually difficult this time, and will wait a more convenient season for developing a definite policy as to making fresh commitments.

OPERATIONS

The general closing of independent steel mills that was predicted in some quarters has not occurred. It is true the rate of operation of the independents as a whole has become very low, averaging perhaps under 25 per cent, but there is not a universal closing. Perhaps half the mills are closed, with those operating running at rates from 25 to 60 per cent.

The United States Steel Corporation is understood to be operating at 92 per cent, or a trifle more, measured by ingots. A very few finishing departments are closed for repairs, but on the other hand some have been working up accumulations of semi-finished material.

WAGES

Wage reductions began to appear some time ago, and it looked as though these were forerunners of a general reduction among the iron and steel producers, or at least among the independents. That impression is now seen to be erroneous. Many steel producers openly express the opinion that the wage reductions made were ill-timed and the example is not being generally followed. It is not a case of producers holding that wages should not be reduced, but that the time is not ripe. It is maintained that the various wage advances more than kept pace with the increase in the cost of living, up to the latter's peak, and that with the decrease in the living cost that has already occurred, with more to follow, the iron and steel producing industry is eventually to be on a materially lower wage basis.

COKE

Additional Connellsville furnace coke contracts for the first half of the new year on the general basis of a 5 to 1 ratio against basic pig iron at valley furnaces have been reported beyond the business noted in last review, and the total is now in the neighborhood of 75,000 tons a month.

Some contracts made a couple of months ago, equivalent to a ratio of about $4\frac{1}{2}$ to 1, are still in existence, but will probably be modified when the furnaces involved have occasion to run. Basic pig iron is quotable nominally at \$33 valley, but the trade is under the impression that at the beginning of January a \$30 price will be recognized by some producers. That would make the coke on a 5 to 1 contract cost \$6, this being regarded as a moderately fair cost in the circumstances, the coke operator having little control over his coal mining cost, which is dictated by the general coal scale even though the Connellsville region is technically non-union. Spot furnace coke can be had without difficulty at \$5.50.

PIG IRON

The pig iron market remains dormant, with merchant furnaces continuing to go out of blast. In western Pennsylvania and Ohio fully half the merchant furnaces are out, and others are to go out shortly. The furnaces accumulate no stocks before blowing out, and as consumers have been reducing their stocks the market situation is very sound in that respect, even though quoted prices almost entirely lack buying support. Quotations are practically nominal at \$35 for foundry and bessemer and \$33 for basic, f.o.b. valley furnaces. It seems safe to predict that next week furnace offerings will establish prices of about \$32 for bessemer and \$30 for basic, while foundry iron may merely sag somewhat.

SEMI-FINISHED STEEL

No interest whatever is manifested in billets and there can hardly be said to be even a nominal market price. In sheet bars all producers are holding firmly to \$47, which is the Industrial Board price of \$42 plus a \$5 advance made last September by the Steel Corporation. It is the contention of some sheet mills that the real market basis is \$42 and that the \$47 price is only temporary. Some customers of the Steel Corporation, however, state that they have received no intimation of an intention to supply sheet bars in 1921 at any other price than \$47. At any rate, some sheet mills are said to be "holding out" for a \$42 price with the independents from whom they usually draw supplies, but a case is yet to be heard of a consumer making a firm bid for a tonnage at \$42.

FINISHED PRODUCTS

In the past few weeks, as already reported, the important finished steel products have declined in the independent market to the Steel Corporation level. Pipe was, and remains, the exception, the independents having a list from \$7 to \$10 a ton above the corporation list. There is a rumor that some of the independents will issue a new and reduced list under date of Jan. 3. Pipe is exceptional among steel products in having shown to date an excellent demand against contracts, with pipe departments generally running full. As the mills should normally carry stocks, there is an opportunity for independents to run on stocks and a reduction in price is not considered absolutely necessary at this time.

RAILS

Contrary to expectations entertained in many quarters, the independent rail mills one by one have reduced their asking prices to the Steel Corporation or Industrial Board level, \$45 per gross ton for bessemer and \$47 for open-hearth. The distribution of rail orders for 1921 replacements will be somewhat heavier in consequence. The Pennsylvania system, which for many years has had almost precisely one-eighth the total ton-mileage of freight movement, has distributed orders for 200,000 tons. The New York Central is taking 175,000 tons or more. It seems safe to predict that the total orders for replacement on the steam roads will be between 1,500,000 and 2,000,000 tons, probably nearer the latter figure. With rails for electric line, industrial use and export, the total output in 1921 is likely to be somewhat over rather than under 3,000,000 tons. This would compare favorably with the average in recent years, but would leave the 4,000,000-ton record of 1906 untouched.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

	Carlots		Less Carlots	
Acetic anhydride.....lb.			\$0.55 - \$0.60	
Acetone.....lb.	\$0.13 - \$0.13 $\frac{1}{2}$		.13 $\frac{1}{2}$ - .14

Aluminum sulphate, iron free.....lb.	.03 $\frac{1}{2}$ - .03 $\frac{1}{2}$		.04 - .04	
Aqua ammonia, 26 deg., drums (750 lb.).....lb.	.06 $\frac{1}{2}$ - .07		.07 $\frac{1}{2}$ - .08 $\frac{1}{2}$	
Ammonia, anhydrous, cyl. (100-150 lb.).....lb.	.33 - .35		.36 - .38	
Ammonium carbonate, powder.....lb.	.14 - .14 $\frac{1}{2}$		.14 $\frac{1}{2}$ - .15	
Ammonium chloride, granular (white salamoniac) (nominal).....lb.	.10 $\frac{1}{2}$ - .11		.11 $\frac{1}{2}$ - .11 $\frac{1}{2}$	
Ammonium chloride, granular (gray salamoniac).....lb.	.1 - .10 $\frac{1}{2}$		.10 $\frac{1}{2}$ - .11	
Ammonium nitrate.....lb.	.09 - .09 $\frac{1}{2}$		.10 - .10 $\frac{1}{2}$	
Ammonium sulphate.....lb.	.03 $\frac{1}{2}$ - .04		.04 - .04 $\frac{1}{2}$	
Amylacetate.....gal.			4.50 - 5.00	
Amylacetate tech.....gal.			3.75 - 4.00	
Arsenic oxide, lumps (white arsenic).....lb.	.10 $\frac{1}{2}$ - .11		.11 $\frac{1}{2}$ - .11 $\frac{1}{2}$	
Arsenic, sulphide, powdered (acid arsenic).....lb.	.15 - .15 $\frac{1}{2}$		.15 - .16	
Barium chloride.....ton	75.00 - 80.00		85.00 - 90.00	
Barium dioxide (peroxide).....lb.	.24 - .25		.26 - .27	
Barium nitrate.....lb.	.10 - .10 $\frac{1}{2}$		.10 $\frac{1}{2}$ - .11	
Barium sulphate (precip.) (blanc fixe).....lb.	.04 $\frac{1}{2}$ - .05		.05 $\frac{1}{2}$ - .06	
Bleaching powder (see calc. hypochlorite).....lb.				
Blue vitriol (see copper sulphate).....lb.				
Borax (see sodium borate).....lb.				
Brimstone (see sulphur, roll).....lb.				
Bromine.....lb.	.50 - .52		.54 - .56	
Calcium acetate.....100 lbs.	2.00 - 2.25			
Calcium carbide.....lb.	.04 - .04 $\frac{1}{2}$		.04 - .05	
Calcium chloride, fused, lump.....ton	30.00 - 32.00		33.00 - 35.00	
Calcium chloride, granulated.....lb.	.02 - .02 $\frac{1}{2}$		.02 $\frac{1}{2}$ - .03	
Calcium hypochlorite (bleaching powder).....lb.	.02 $\frac{1}{2}$ - .03		.03 $\frac{1}{2}$ - .03 $\frac{1}{2}$	
Calcium peroxide.....lb.			1.25 - 1.30	
Calcium phosphate, monobasic.....lb.			.18 - .20	
Calcium sulphate, pure.....lb.			.07 - .08	
Camphor.....lb.			.90 - .95	
Carbon disulphide.....lb.	.08 - .08 $\frac{1}{2}$		.09 - .09 $\frac{1}{2}$	
Carbon tetrachloride, drums.....lb.	.11 - .11 $\frac{1}{2}$		.11 $\frac{1}{2}$ - .12	
Carbonyl chloride (phosgene).....lb.			.60 - .75	
Caustic potash (see potassium hydroxide).....lb.				
Caustic soda (see sodium hydroxide).....lb.				
Chlorine, gas, liquid-cylinders (100 lb.).....lb.	.09 - .09 $\frac{1}{2}$		.10 - .10 $\frac{1}{2}$	
Chloroform.....lb.			.43 - .50	
Cobalt oxide.....lb.			3.90 - 4.00	
Copperas (see iron sulphate).....lb.				
Copper carbonate, green precipitate.....lb.	.22 - .22 $\frac{1}{2}$		.24 - .25	
Copper cyanide.....lb.			.50 - .60	
Copper sulphate, crystals.....lb.	.06 $\frac{1}{2}$ - .06 $\frac{1}{2}$		.07 - .07 $\frac{1}{2}$	
Cream of tartar (see potassium bitartrate).....lb.				
Epsom salt (see magnesium sulphate).....lb.				
Ethyl Acetate Com. 85%.....gal.			1.05 - 1.10	
Ethyl Acetate pure (acetic ether 98% to 100%).....gal.				
Formaldehyde, 40 per cent.....lb.	.18 $\frac{1}{2}$ - .18 $\frac{1}{2}$		.19 - .19 $\frac{1}{2}$	
Fusel oil, ref.....gal.			3.50 - 3.60	
Fusel oil, crude.....gal.			2.75 - 3.00	
Glauber's salt (see sodium sulphate).....lb.				
Glycerine, C. P. drums extra.....lb.			.20 - .21	
Iodine, resublimed.....lb.			3.85 - 4.00	
Iron oxide, red.....lb.			.10 - .20	
Iron sulphate (copperas).....100 lb.	1.50 - 1.75		2.00 - 2.25	
Lead acetate, normal.....lb.			.13 $\frac{1}{2}$ - .16	
Lead arsenate (paste).....lb.	.13 - .14		.14 $\frac{1}{2}$ - .15	
Lead nitrate, crystals.....lb.			.90 - 1.00	
Litharge.....lb.	.10 - .10 $\frac{1}{2}$		.10 $\frac{1}{2}$ - .11 $\frac{1}{2}$	
Lithium carbonate.....lb.			1.50 -	
Magnesium carbonate, technical.....lb.	.10 $\frac{1}{2}$ - .11		.11 $\frac{1}{2}$ - .12	
Magnesium sulphate, U. S. P.....100 lb.	3.00 - 3.25			
Magnesium sulphate, commercial.....100 lb.			1.50 - 1.75	
Methanol, 95%.....gal.			1.75 - 1.80	
Methanol, pure.....gal.			2.10 - 2.15	
Nickel salt, double.....lb.			.12 - .12 $\frac{1}{2}$	
Nickel salt, single.....lb.			.13 - .13 $\frac{1}{2}$	
Phosgene (see carbonyl chloride).....lb.				
Phosphorus, red.....lb.	.35 - .37		.38 - .40	
Phosphorus, yellow.....lb.			.35 - .37	
Potassium bichromate.....lb.	.17 $\frac{1}{2}$ - .17 $\frac{1}{2}$		.18 - .18 $\frac{1}{2}$	

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar).... lb.	\$.. - \$....	\$0 38-\$0.40
Potassium bromide, granular..... lb.	.. - ..	.35 - .40
Potassium carbonate, U. S. P..... lb.	.35 - .40	.45 - .50
Potassium carbonate, crude..... lb.	.11 - .11½	.11½ - .12
Potassium chlorate, crystals..... lb.	.12 - .13	.13½ - .18
Potassium cyanide..... lb.	.. - ..	.65 - .70
Potassium hydroxide (caustic p. tash).... lb.	.14 - .14½	.15 - .16
Potassium muriate..... ton	75.00 - 80.00	.. - ..
Potassium iodide..... lb.	.. - ..	3 00 - 3.20
Potassium nitrate..... lb.	.11 - .12	.12½ - .13
Potassium permanganate..... lb.	.60 - .63	.65 - .70
Potassium prussiate, red..... lb.	.55 - .57	.58 - .60
Potassium prussiate, yellow..... lb.	.32 - .32½	.33 - .33½
Potassium sulphate (powdered)..... ton	\$225.00 - 230.00	.. - ..
Rochelle salts (see sodium potas. tartrate)	.. - ..	.. - ..
Salammoniac (see ammonium chloride).....	.. - ..	.. - ..
Sal soda (see sodium carbonate).....	.. - ..	.. - ..

Sulphur, roll (brimstone)..... 100 lb.	.. - ..	3.40 - 3.90
Tin bichloride, 50 per cent..... lb.	.18 - .19	.. - ..
Tin oxide..... lb.	.. - ..	.50 - .51
Zinc carbonate, precipitate..... lb.	.16 - .18	.19 - .20
Zinc chloride, gran..... lb.	.12 - .13	.13½ - .14
Zinc cyanide..... lb.	.45 - .49	.50 - .60
Zinc dust..... lb.	.12 - .13	.13½ - .14
Zinc oxide, XX..... lb.	.10 - .10½	.11 - .11½
Zinc sulphate..... lb.	.03½ - .03½	.04 - .06

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.10 - \$1.15
Alpha-naphthol, refined..... lb.	1.45 - 1.50
Alpha-naphthylamine..... lb.	.40 - .44
Aniline oil, drums extra..... lb.	.22 - .26
Aniline salts..... lb.	.27 - .30
Anthracene, 80% in drums (100 lb.)..... lb.	.90 - 1.00
Benzaldehyde (f.f.c.)..... lb.	2.00 - 2.10
Benzidine, base..... lb.	1.00 - 1.10
Benzidine sulphate..... lb.	.85 - .90
Benzoic acid, U.S.P..... lb.	.70 - .75
Benzoate of soda, U.S.P..... lb.	.75 - .85
Benzene, pure, water-white, in drums (100 gal.) gal.	.32 - .35
Benzene, 90% in drums (100 gal.)..... gal.	.30 - .32
Benzyl chloride, 95-97%, refined..... lb.	.35 - .40
Benzyl chloride, tech..... lb.	.25 - .35
Beta-naphthol benzoate..... lb.	3.50 - 4.00
Beta-naphthol, sublimed..... lb.	.75 - .80
Beta-naphthol, tech (nominal)..... lb.	.40 - .45
Beta-naphthylamine, sublimed..... lb.	2.25 - 2.40
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 - .18
Ortho-cresol, in drums (100 lb.)..... lb.	.23 - .25
Cresylic acid, 97-99%, straw color, in drums..... gal.	.95 - 1.00
Cresylic acid, 95-97%, dark, in drums..... gal.	.90 - .95
Cresylic acid, 50%, first quality, drums..... gal.	.65 - .75
Dichlorobenzene..... lb.	.07 - .15
Diethylaniline..... lb.	1.35 - 1.40
Dimethylaniline..... lb.	.65 - .90
Dinitrobenzene..... lb.	.30 - .37
Dinitrochlorobenzene..... lb.	.25 - .30
Dinitronaphthalene..... lb.	.40 - .45
Dinitrophenol..... lb.	.40 - .45
Dinitrotoluene..... lb.	.30 - .32
Dip oil, 25%, tar acids, car lots, in drums..... gal.	.38 - .40
Diphenylamine..... lb.	.70 - .75
H-acid..... lb.	1.40 - 1.55
Meta-phenylenediamine..... lb.	1.25 - 1.30
Monochlorobenzene..... lb.	.15 - .16
Monoethylaniline..... lb.	1.75 - 2.25
Naphthalene crushed, in bbls. (250 lb.)..... lb.	.08 - .08½
Naphthalene, flake..... lb.	.08 - .08½
Naphthalene, balls..... lb.	.09 - .09½
Naphthionic acid, crude..... lb.	.70 - .75
Nitrobenzene..... lb.	.12 - .15
Nitro-naphthalene..... lb.	.40 - .50
Nitro-toluene..... lb.	.18 - .25
Ortho-amidophenol..... lb.	3.20 - 3.75
Ortho-dichlor-benzene..... lb.	.15 - .20
Ortho-nitro-phenol..... lb.	.75 - .80
Ortho-nitro-toluene..... lb.	.23 - .30
Para-amidophenol, base..... lb.	.25 - .30
Para-amidophenol, HCl..... lb.	2.20 - 2.25
Para-amidophenol, HCl..... lb.	2.10 - 2.15

Para-dichlorobenzene..... lb.	.10 - .15
Paranitroaniline..... lb.	.93 - 1.00
Para-nitrotoluene..... lb.	1.25 - 1.40
Para-phenylenediamine..... lb.	2.20 - 2.35
Para-toluidine..... lb.	1.70 - 1.80
Phthalic anhydride..... lb.	.60 - .70
Phenol, U. S. P., drums (dest.), (240 lb.)..... lb.	.09 - .10
Pyridine..... gal.	2.00 - 3.50
Resorcinol, technical..... lb.	2.75 - 2.80
Resorcinol, pure..... lb.	3.60 - 3.80
Salicylic acid, tech., in bbls. (110 lb.)..... lb.	.32 - .33
Salicylic acid, U. S. P..... lb.	.35 - .37
Salol..... lb.	.85 - .95
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.30 - .35
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.19 - .22
Sulphanilic acid, crude..... lb.	.32 - .35
Tolidine..... lb.	1.35 - 1.40
Toluidine, mixed..... lb.	.45 - .55
Toluene, in tank cars..... gal.	.30 - .32
Toluene, in drums..... gal.	.33 - .35
Xylidines, drums, 100 gal..... lb.	.45 - .50
Xylene, pure, in drums..... gal.	.42 - .45
Xylene, pure, in tank cars..... gal.	.45 - .48
Xylene, commercial, in drums, 100 gal..... gal.	.37 - .38
Xylene, commercial, in tank cars..... gal.	.30 - ..

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark..... lb.	\$0.26 - \$0.27
Beeswax, refined, light..... lb.	.28 - .30
Beeswax, white pure..... lb.	.35 - .40
Carnauba, No. 1..... lb.	.85 - .90
Carnauba, No. 2, North Country..... lb.	.45 - .50
Carnauba, No. 3, North Country..... lb.	.20 - .25
Japan..... lb.	.19 - .20
Montan, crude..... lb.	.07 - .08
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.06½ - .06½
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.06½ - .06½
Paraffine waxes, refined, 118-120 m.p..... lb.	.07 - .07
Paraffine waxes, refined, 125 m.p..... lb.	.07½ - .08
Paraffine waxes, refined, 128-130 m.p..... lb.	.08½ - .09
Paraffine waxes, refined, 133-135 m.p..... lb.	.10 - .11
Paraffine waxes, refined, 135-137 m.p..... lb.	.11½ - .12
Stearic acid, single pressed..... lb.	.14½ - .15
Stearic acid, double pressed..... lb.	.15½ - .15½
Stearic acid, triple pressed..... lb.	.16 - .16½

Flotation Oils

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr., 0.930-0.940..... gal.	\$1.90
Pine oil, pure, dest. dist..... gal.	1.50
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.48
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75
Pine tar, ref., thin, sp.gr., 1.080-1.960..... gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970..... gal.	1.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990..... gal.	.35
Pinewood creosote, ref..... gal.	.52

Naval Stores

The following prices are f.o.b. New York for carload lots.

Rosin B- , bbl..... 280 lb.	\$8.75 - ..
Rosin E-I..... 280 lb.	8.75 - ..
Rosin K-N..... 280 lb.	8.75 - ..
Rosin W. G.-W. W..... 280 lb.	9.00 - ..
Wood rosin, bbl..... 280 lb.	9.00 - ..
Spirits of turpentine..... gal.	.76 - ..
Wood turpentine steam dist..... gal.	.74 - ..
Wood turpentine, dest. dist..... gal.	.74 - ..
Pine tar pitch, bbl..... 200 lb.	.. - 8.50
Tar, kiln burned, bbl. (500 lb.)..... bbl.	.. - 15.00
Retort tar, bbl..... 500 lb.	15.00 - 15.50
Rosin oil, first run..... gal.	.60 - ..
Rosin oil, second run..... gal.	.62 - ..
Rosin oil, third run..... gal.	.75 - ..

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.41
70-72 deg., steel bbls. (85 lb.)..... gal.	.39
68-70 deg., steel bbls. (85 lb.)..... gal.	.38
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.30

Crude Rubber

Para-Upriver fine..... lb.	\$0.18½ - \$0.19
Upriver coarse..... lb.	.14 - .14½
Upriver caucho ball..... lb.	.14½ - .14½
Plantation—First latex crepe..... lb.	.17 - ..
Ribbed smoked sheets..... lb.	.16½ - ..
Brown crepe, thin, clean..... lb.	.16 - ..
Amber crepe No. 1..... lb.	.17 - ..

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.10 - \$0.11½
Castor oil, AA, in bbls..... lb.	.12 - .13
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.09 - .09½
Cocanut oil, Ceylon grade, in bbls..... lb.	.13 - .13½
Cocanut oil, Cochín grade, in bbls..... lb.	.13½ - .14
Cori oil, crude, in bbls..... lb.	.09 - .09½
Cottonseed oil, crude (f. o. b. mill)..... lb.	.06 - .07
Cottonseed oil, summer yellow..... lb.	.08½ - .08½
Cottonseed oil, winter yellow..... lb.	.09 - .09½
Linseed oil, raw, car lots (domestic)..... gal.	.77 - .79
Linseed oil, raw, tank cars (domestic)..... gal.	.73 - .74
Linseed oil, boiled, car lots (domestic)..... gal.	.78 - .80

Olive oil, commercial.....	gal.	2.60	—	2.70
Palm, Lagos.....	lb.	.07 $\frac{1}{2}$	—	.08
Palm, Niger.....	lb.	.07 $\frac{3}{4}$	—	.08 $\frac{1}{2}$
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.07	—	.07 $\frac{1}{2}$
Peanut oil, refined, in bbls.....	lb.	.13	—	.13 $\frac{1}{2}$
Rapeseed oil, refined in bbls.....	gal.	1.10	—	1.15
Rapeseed oil, blown, in bbls.....	gal.	1.20	—	1.25
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.08 $\frac{1}{2}$	—	.09
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.06	—	.07

FISH

Light pressed Menhaden.....	gal.	\$0.53	—	\$0.55
Yellow bleached Menhaden.....	gal.	.55	—	.58
White bleached Menhaden.....	gal.	.57	—	.60
Blown Menhaden.....	gal.	1.00	—	

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	\$24.00	—	\$30.00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	22.00	—	26.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

EL CENTRO—The City Council plans an election in January to vote on \$125,000 to purchase and enlarge the present privately owned gas plant. W. F. Holt, principal owner.

LOS ANGELES—The Consolidated Vanadium Co., 1225 Washington Bldg., has awarded the contract for the construction of a 1-story, 50x50-ft. factory for the manufacture of vanadium products, to the Union Iron Works, 5125 Santa Fe Ave., Estimated cost, \$4,000.

Massachusetts

WAKEFIELD—The town plans to install equipment in the gas plant of the municipal light plant. Estimated cost, \$250,000.

Colorado

LA JUNTA—The town plans an election Jan. 20 to vote on \$200,000 bonds to construct a high school. A chemical laboratory will be installed in same.

Georgia

CREST—The Taylor Graphite Co. plans to install mining and concentrating equipment. Estimated cost, \$23,000. J. E. Taylor, pres.

Iowa

CHARLES CITY—The city is having plans prepared for the construction of a sewage disposal plant. Estimated cost, \$25,000. W. E. Buell, 228 Davidson Bldg., Sioux City, engr.

DECORAH—The Bd. Educ. plans an election Jan. 10 to vote on \$150,000 bonds to construct a 2- or 3-story high school. A chemical laboratory will be installed in same. C. F. Barefoot, secy.

KEOKUK—The city plans an election soon to vote on \$500,000 bonds to build a 3-story high school. A chemical laboratory will be installed in same. F. C. Smith, secy.

Maryland

BALTIMORE—The School Bd. of Awards has awarded the contract for the construction of a 3-story, 76x271-ft. high school on Latrobe Park and Fort Ave., to the Standard Constr. Co., 1713 Sansom St., Philadelphia, Pa. A chemical laboratory will be installed in same.

Minnesota

NEW PRAGUE—J. E. Bruzek, city clk., will soon receive bids for the construction of a sewage disposal plant. Estimated cost, \$50,000. J. W. Shaffer & Co., 917 New York Life Bldg., Minneapolis, engr.

NORTHFIELD—St. Olaf's College plans to build a 3-story, 73x186-ft. science hall. A chemical laboratory will be installed in same. Estimated cost, \$500,000. N. E. Mohn, 596 Endicott Bldg., St. Paul, archt.

RENVILLE—A. R. Holmberg, clk. of the Bd. Educ. will receive bids until Jan. 18 for the construction of a 2-story, 146x273-ft. grade and high school. Estimated cost, \$280,000. Croft & Boerner, 1006 Marquette Ave., Minneapolis, archts.

Montana

MILES CITY—The Bd. Educ., c/o Olive Lovett, Supt. of Schools, has had plans prepared for the construction of a 3-story high school. A chemical laboratory will be installed in same. Estimated cost, \$400,000.

New Jersey

NEWARK—The Butterworth-Judson Corp., Doremus Ave., has had plans prepared for the reconstruction of a 3-story paranitraniline unit of its plant which was recently destroyed by fire. Estimated cost, \$180,000.

North Dakota

BISMARCK—The city will soon award the contract for the construction of a waterworks system to include reservoirs, filtration plant, pumping station, distributing system, etc. Estimated cost, \$1,300,000. L. R. Wolff, 1000 Guardian Life Bldg., St. Paul, Minn., engr. Noted June 30.

Ohio

HOLGATE—The town will receive bids until Jan. 8 for altering and building a 2-story, 66x155-ft. addition to the high school. Chemical equipment will be installed in same. Estimated cost, \$90,000. O. L. C. Zachsich, clk. S. P. Stewart & Son, Bowling Green, archts.

Oklahoma

VINITA—The city has had plans prepared for the construction of a purification plant to include liquid chlorine treatment and sand filters, etc. Estimated cost, \$460,000. H. G. Olmsted & Co., 417 Oil Exch., Oklahoma City, engr. Noted Nov. 24.

South Dakota

MCINTOSH—The Bd. Educ. will receive bids until Jan. 24 for the construction of a 2-story grade and high school. A chemical laboratory will be installed in same. Estimated cost, \$150,000. E. J. Geers, clk. G. Issenhuth, Huron, archt.

Virginia

NORFOLK—The Western Junior High School plans to build a 4-story, 150x310-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$700,000.

Wisconsin

DURAND—The Bd. Educ., c/o H. A. Miles, secy., is having plans prepared for the construction of a 2-story, 80x124-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$100,000. Oppenhamer & Obel, Wausau, archts. Noted Aug. 25.

FOND DU LAC—The Bd. Educ., c/o A. M. Hunter, secy., has had plans prepared for the construction of a 3-story, 110x115-ft. senior high school on Linden St. A chemical laboratory will be installed in same. Estimated cost, \$275,000. Childs & Smith, 64 East Van Buren St., Chicago, archts.

HARTFORD—The city retained J. Donohue, engr., 720 New York Ave., Sheboygan, to prepare plans for altering the sewerage system, building septic tank, etc. Estimated cost, \$50,000. W. Radke, city clk.

KIMBERLY—The city engaged F. A. C. Smith, engr., Colby-Abbott Bldg., Milwaukee, to prepare plans for the construction of a sewerage system and sewage disposal plant. Estimated cost, \$100,000.

MILWAUKEE—T. Rogers, chemist, c/o Dept. of Pub. Wks., plans to install \$15,000 worth of special equipment in the garbage plant for the purpose of determining the practicability of making alcohol from garbage.

OCONTO FALLS—The Bd. Educ., c/o G. Krohn, secy., is having plans prepared for the construction of a 1-story, 76x100-ft. high and grade school on Main St. A chemical laboratory will be installed in same. Estimated cost, \$100,000. Juul & Smith, Imig Bldg., Sheboygan, archts.

WEST ALLIS—The City Council plans to build an addition to the septic tank. Estimated cost, between \$15,000 and \$25,000. A. Schneider, City Hall, engr.

Ontario

SMITHS FALLS—The town plans to construct a filtration plant. Estimated cost, \$15,000. J. A. Lewis, clk.

Quebec

MONTREAL—The Can Welding Co., Amherst St. near Ontario St., plans to construct a plant, including equipment. Estimated cost, \$60,000.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its annual meeting Feb. 21 to 24, 1921, at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29, 1921.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting Feb. 14 to 17 in New York City.

COMMON BRICK MANUFACTURERS' ASSOCIATION OF AMERICA will hold its annual meeting at the Hotel Pennsylvania, New York City, Jan. 31 to Feb. 4.

COMPRESSED GAS MANUFACTURERS' ASSOCIATION will hold its eighth annual meeting, Monday, Jan. 17, 1921, at 2 p.m., at the Hotel Astor, New York, and its eighth annual dinner at the same place that evening.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetter's Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF CHEMICAL INDUSTRY holds its Perkin Medal Award Meeting at Rumford Hall, Chemists' Club, New York, on Jan. 14, 1921.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: Jan. 7, American Chemical Society; Jan. 14, Society of Chemical Industry, Perkin Medal award; Feb. 11, American Electrochemical Society, joint meeting with Society of Chemical Industry, American Chemical Society and Société de Chimie Industrielle; March 11, American Chemical Society, Nichols Medal award; March 25, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Industrial Notes

THE JAPANESE TISSUE MILLS, INC., of Holyoke, Mass., which is a combination of the former Mt. Holyoke Tissue and Japanese Tissue Mills, has changed its name to the American Tissue Mills. Important changes are being made in the company.

THE AMHERST WAXED PAPER CO., Amherst, Mass., is preparing to locate in Holyoke, Mass., in a building constructed some time ago by J. L. Perkins, who purchased the company some years back. The new mill is being fitted up with waxed paper machinery and will employ 100 hands when operating to full capacity. The present mill is located at Amherst and will be retained for some time to come.

THE CIVIC AND COMMERCIAL ASSOCIATION of Denver, Col., is making a research study for the porcelain industry for the benefit of the city; Homer B. Vanderblu, of the industrial research department, is spending three weeks in the ceramic industries, particularly at Liverpool, O. He will make arrangements for the testing of Colorado clays by the experts of the Ohio region and investigation as to the various possible uses in the manufacture of porcelain. Technical investigations will later be made in cooperation with the Colorado Society of Engineers, which has offered to participate in the work.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO., East Pittsburgh, Pa., has initiated a part-time employment plan, in order that engineering students of the University of Pittsburgh and the Carnegie Institute of Technology may be able to gain practical knowledge regarding the production and testing of electrical apparatus, and at the same time earn extra money. Students are allowed the regular hourly rate for work on Saturday afternoons, Sunday and holidays. For the most part the employment consists of store-keeping, which allows the students to become familiar with the size and character of the different kinds of electrical apparatus.

THE STAR BRASS WORKS, 3114-28 Carroll Ave., Chicago, announces that on and after Jan. 1, 1921, the company name will be changed to Binks Spray Equipment Co. Such change of name has been made to conform more nearly with the nature of the products manufactured. Simultaneously announcement is also made of the completion of a new plant and office extension on the west wing of the old plant in which provisions are made for new salesroom, testing laboratories, and greatly increased manufacturing facilities on the first floor, with new offices and drafting rooms on the second floor. This company also announces the establishment of a Pacific Coast office in charge of L. M. Page, Rialto Bldg., San Francisco.

THE MAX-LEW CHEMICAL CO., of 20 Clinton St., Newark, N. J., with David E. Bernstein as agent, has been chartered in the office of the Secretary of State to operate in New Jersey in the manufacture and sale of chemicals, alkalis, etc., as some of its principal objects. The concern has a capitalization of \$100,000, which is divided into 1,000 shares at \$100 each, while the amount that will be devoted to the starting of business is \$3,000. The incorporators and the number of shares held by each are Max Lewitt, of 68 Howard St., Newark, N. J., 10; George Lewitt, of 68 Howard St., Newark, N. J., 10, and Abraham Lewitt, of 68 Howard St., Newark, N. J., 10.

THE METAL & THERMIT CORP., New York, announces that O. E. Falls, who has had many years of experience in charge of foundry and thermit welding work at the Norfolk Navy Yard, Portsmouth, Va., has accepted a position with it. Announcement is also made of the opening of a branch office at 141 Milk St., Boston, in charge of Robert L. Browne.

THE ELECTRIC FURNACE CO., Alliance, O., has just shipped two 165-kw. Baily units to Norway, where they will be used to melt zinc at the Jossingfyord plant in Stavanger, and to melt aluminum at the Norsk Aluminium Works at Christiania. Complete rolling mill brass-melting furnaces, designed for pouring the metal directly into the molds, have recently been shipped by this company to the Amsinck Corp. of Mexico, Mitsui & Co. of Japan, and Allen Everett, Ltd., of England. In addition to these units Baily electric furnaces have recently been installed at three Canadian plants: The Dominion Steel Products Co. of Brantford, Ont., the Monarch Metals Co. of Hamilton, Ont., and the Union Screen Plate Co. of Lennoxville, Que.

S., 1918, Part II), published July 14, 1920; II: 33, Abrasive Materials in 1918, by Frank J. Katz (Mineral Resources of the U. S., 1918, Part II), published Aug. 27, 1920; II: 34, Stone in 1918, by G. F. Loughlin and A. T. Coons (Mineral Resources of the U. S., 1918, Part II), published Oct. 11, 1920.

Manufacturers' Catalogs

AMERICAN TERRA COTTA CO., Chicago, Ill., is now publishing a house organ entitled *Common Clay*, which deserves special mention as to reading matter and illustrations. W. D. Gates, president of the company and dean of Chicago ceramists, writes a department called "Button-hole Talks." These talks are bits of philosophy well worth reading. The American Terra Cotta Co. manufactures art and ornamental terra cotta and the publication is a successful exposition of the company's artistic developments.

CLARENCE W. MARSH, 101 Park Ave., New York City, has published an instructive folder on the Marsh electrolytic cell for chlorine and caustic soda.

W. S. ROCKWELL CO., New York, calls attention to Bull. 222. In this bulletin the purpose is not to talk about furnaces of the company's manufacture, but to place before the furnace-using public the principles drawn from the company's experience, prints of actual installations being used to illustrate the points raised. Such points include: The applicability of car-type and car-and-ball type furnaces to the heat-treatment of material that cannot be advantageously handled in other types of furnaces; factors governing selection of the type (car or car-and-ball) best suited to individual manufacturing requirements; the difference in design of each type; influence of unequal cooling on the quality of finished product; typical heat-treatment installations involving the use of car-type and car-and-ball type furnaces.

THE METAL & THERMIT CORP., New York, has just issued and will distribute on request the third edition of the Thermit Welding pamphlet No. 17 for mill and foundry repairs. The new edition has been revised and brought up to date both as regards new practices recommended and illustrations showing recent interesting repairs on certain types of equipment since the publication of the former edition. The pamphlet begins with a general discussion of the proper applications and fields for oxy-acetylene, electric and thermit welding, respectively. It then describes in detail the methods to be followed and apparatus used in welding iron and steel sections in general. Later it outlines thoroughly special applications of thermit welding, such as for crankshaft, pinion and roll repairs and also for cast-iron welding. Not previously included in former editions of this pamphlet is a description of a new method of welding teeth in pinions. The pamphlet

concludes by explaining the various applications of thermit in foundry practice, such as for increasing the temperature of iron and steel, facilitating the introduction of other metals which it is desired to alloy for special purposes, making semi-steel in the ladle, keeping metal and risers liquid for a considerable period and making small steel castings. This company also announces a revised Thermit Rail Welding pamphlet, No. 39, which describes the various ways in which thermit welding can be advantageously used for rail welding, and pamphlet No. 20 on thermit carbon-free metals and alloys. The pamphlet, in addition to containing a detailed description of the properties and characteristics of the various carbon-free metals and alloys manufactured by this company, includes an explanation of the advantages of using Tungstabs, or tablets of pure tungsten metal, in the production of high-speed steel and other alloys containing tungsten instead of using tungsten powder and ferrotungsten. Metallurgical losses caused by oxidation in melting and by the absorption of tungsten by the crucible and electric-furnace lining, particularly in the initial heats, are reduced because by using Tungstabs the melting time is decreased and there is a higher recovery of the tungsten owing to the fact that the Tungstabs melt down with the charge.

THE JOSEPH T. RYERSON & SONS CO., Chicago, has issued a leaflet entitled "Do You Know How to Make a Chisel?" which contains a complete description of working, grinding, hardening and tempering the ordinary hand chisel, and will be found of interest to anyone who has to do with the use of chisels generally.

THE BOOTH ELECTRIC FURNACE CO., Chicago, has issued a handsomely illustrated catalog describing the Booth rotating furnaces, giving a list of plants where these are installed. Tables of dimensions of the several sizes appended to blueprints give an accurate idea of the details of construction.

THE MANUFACTURERS' EQUIPMENT CO., Dayton, O., has issued a new bulletin entitled "The Underwood Producer Gas System," which contains descriptions of apparatus and application for burning all kinds of clay products, for glass house furnaces, steel furnaces, the making of carbon products, the heating of enameling furnaces, and the heating of furnaces in chemical and acid plants. The pamphlet contains technical data interesting to those engaged in the above industries.

THE CLEVELAND BREATHING MACHINE CO., Cleveland, O., has issued a 4-page folder on "The Lyon Breathing Machine."

THE CUTLER-HAMMER MFG. CO., Milwaukee, Wis., announces that in order to include information under one cover on C-H products for mine applications a new 48-page illustrated booklet has been prepared, which is entitled "For the Mine." Attention is also called to Publication 867, entitled "Dictionary of Uses" of C-H Electric Space Heaters.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO., East Pittsburgh, Pa., has just received from the Press Bull. 7-A-C-1 on "Mine Locomotive Headlights."

OXWELD ACETYLENE CO., Chicago, Ill., is issuing its new "Ever-ready" instruction book, which is a treatise on every-day oxy-acetylene welding and cutting. This volume, which is 5x8 in., contains fifty-five printed pages, inclusive of illustrations and drawings.

PLANT ENGINEERING & EQUIPMENT CO., New York City, calls attention to a new catalog on Peeco Equipment, which gives illustrations and descriptions of its steam trap gages, valve steam traps, turbo-blowers for steam boilers, Mason condensation meter, etc.

DODGE SALES & ENGINEERING CO., Mishawaka, Ind., has issued Catalog D-20-C on Standardized Elevators and Conveyors, continuous mechanical handling, which is very complete and gives illustrations as well as descriptions.

THE BROWN HOISTING MACHINERY CO., Cleveland, O., has published Catalog K 1921, on Locomotive Cranes. This attractive 88-page catalog illustrates and describes the many types of cranes and equipment.

BLAKE PUMP & CONDENSER CO., Fitchburg, Mass., desires to announce Catalog H-40, on "High-Efficiency Pumping Machinery." The predominating feature of the pumping apparatus shown in this catalog is the application of the Blake-Fitchburg high-efficiency four-bearing type power end to certain types of fluid ends which have been developed to a high efficiency for the particular service to which they are applicable. Many interesting illustrations are given of the different types.

New Hearings on The Patent Office Bill

WHILE no new arguments against section 9 of the Patent Office bill were offered at the hearings before the joint conference committee of the House and Senate, reported elsewhere in this issue, industrial chemical concerns took advantage of their first opportunity to apprise Congress of their views. They appeared in large numbers, representing the leading manufacturers whose interests are considered jeopardized by the proposal to patent the inventions of Government employees and administer these patents through license by the Federal Trade Commission. In our issue for Oct. 27, 1920, we devoted a great deal of space to the subject, and but little can be added here to the pros and cons there given.

Viewing the matter after this lapse of time and in the light of the representations before the committee at Washington, it is still quite evident that there are some features of the proposal which are rightly objectionable to industry. Even though the measure should fail to function—a probability frankly advanced by unbiased as well as partisan witnesses—its administration involves principles which are repugnant to business men. Will the Federal Trade Commission grant exclusive or non-exclusive licenses? If the latter, none are likely to be taken; if the former, there must inevitably be protest against favoritism. Projecting ourselves into the future operation of the measure, it would seem as though exclusive licenses will be essential to its operation. Non-exclusive licenses will gain nothing more than is now obtained by dedication to the public. Again, what is the proper disposition of useful knowledge gained by Government employees occupied in official duties at public expense? Shall it be parceled out discriminately? And if so, who shall be the fortunate recipient of the product of a public servant's toil? The practical consequence must be confusion, crimonations and re-criminations.

Further, what is the legitimate field of research for the Government? Should it be in those lines of industry which will yield patentable inventions that will require some special method of administration in the public industry? Shall industry be further encouraged to conduct its own research, using such media as consulting scientists and industrial laboratories, or shall it be discouraged from this course and led to look to the Government for its progress? Admitting that there are now some industries so poorly developed or existing in large numbers of small units, so that they need a correlating agency to assist them, is not the whole idea of industrial research so well developed that in most instances the Government could rely on established private agencies to do the necessary work, and even refer industries to such agencies?

While it is problematical what the joint conference

committee will do as a result of the opposition to section 9, we may hazard a guess that it will retain the measure in the bill in spite of the unanimous opposition of industry. The opposition will be discounted on the ground that it represents the selfish interest of large and greedy corporations that wish to stifle Government investigation in the interest of the people. The rôle of the corporations is unpopular, in spite of the fact that they have done and are doing much to advance industrial research which ultimately benefits the consuming public. Nor will the conference committee consent to separate section 9 from the bill for relief of the Patent Office, because thus separated it will have no chance of passage at this session of Congress. Full advantage will be taken of the opportunity of putting the section through as a rider to a measure which has the indorsement of all the people.

When Will Activity In General Business Return?

THE question asked in the caption to these remarks is one that is being heard on all hands, and a wide variety of answers is being given, most of them distinctly evasive. As a rule there is a close connection between the character of answer and the individuality of the one suggesting the answer. The man who has been worrying for a year or two about the high wages the country has been paying answers that activity in business will be restored when wages come down. The man whose hobby is crops and the Western farmers says the farmer owes a great deal of money to the banks and cannot buy until he has paid off his notes, so that it will be a long time before we have business activity. The man who has always considered the railroads the chief source of prosperity in the country holds that activity will return when the railroads begin to buy, but has doubts whether they will do so soon, and so on and so on.

As a test of the prophet's trustworthiness it would be very useful to find out what the man thought six months ago. Probably in nine cases out of ten it would be found that the man who now sets the longest time for the return of activity is the man who six months ago was most strongly convinced that the business conditions of that time were marked for indefinite continuance.

There are men who can be got to admit that in the past few weeks as they have seen prices drop more than they expected and more factories close than they had looked for, they have increased their estimate of the time that will elapse before the wheels of industry are turning freely again. They admit that we are engaged in a process of readjusting. When they see readjustment proceeding rapidly and thereupon lengthen the time estimated for completion of the process they tacitly admit that they had no idea of the extent of the

readjustment requisite, for if the readjustment had a fixed distance to go, the quicker it moved the sooner it would reach the objective.

It seems fairly clear that the readjustment through which we are passing is one of mental attitudes, and such a process does not require a long period of time. Men must become willing to do a bigger day's work and receive only reasonable wages for the day's work. Retailers, wholesalers and manufacturers must become content with moderate profits. An idle workman does not require a long period of idleness for a change of mind. The retailer, particularly if his customers have no jobs, can change his philosophy quite suddenly. There are manufacturers who have closed their plants with the thought that they have accumulated safe reserves and will not resume operations until offered their former profits, but it is not in human nature to enjoy the spectacle of an idle plant for any length of time. The mental reactions can occur in rather a short time. Then there are the buyers, who have gone on strike. They know what they went on strike for—lower prices—but they do not know how much lower. Idleness will become irksome to them also and they will be willing to compromise.

The idea that the readjustment is one of mental attitudes rather than of physical conditions is reinforced by contemplation at long range of mental attitudes during and since the war. Toward the close of the war the majority of people thought that commodity prices would decline immediately after the war, but there were not a few who expected prices to advance very sharply. As a matter of fact, prices did decline after the armistice, and then afterward they advanced a great deal. Evidently there was a very unstable mental condition.

A very common prediction during the war had been that there would be a "transitionary period" while things were getting changed from a war-time to a peace-time basis, and then a prolonged era of great prosperity. We have not had that era of prosperity and there is no proof that we cannot have it. The transition was made difficult by men not taking hold in the right way. First there was fear and then there was inordinate greed, both mental attitudes and both very objectionable. Now we are booked to get into a new mental attitude, and the process does not necessarily require a long period of time.

Beware the

Ides of March!

THE present Chief of Staff, General PEYTON C. MARCH, apparently still continues his opposition to proper development of Chemical Warfare Service. In this he is seemingly well supported by the present Secretary of War. However, with the change of Administration we may expect a change in this, as in many other governmental conditions. Indeed, about Washington one hears the very pointed sentence, "March fourth, forth goes MARCH."

One may even believe that it is not committing *lèse majesté* to hope that there will promptly be a selection of a new Chief of Staff who really appreciates and will support (as required by law) the Chemical Warfare Service. The recent report of the special commission headed by General PERSHING to select eligibles for the General Staff affords ample good material for this purpose.

Timeo Danaos

Et Dona Ferentes

HAVE you heard of the "Friends of Science, interested in its development"? If not you may yet entertain angels unawares. And if you have not seen the salmon-colored sheet of propaganda for German scientific porcelain, glassware and apparatus, issued by the aforesaid Friends, you have missed an amateurish effort at camouflage that is not very convincing. Anyhow our anonymous Friends are solicitous for the welfare of American colleges and universities, and bemoan the proposed surrender of the privilege which those institutions have enjoyed of importing scientific apparatus and instruments duty free. The Friends would have the privilege retained because it means a continuance of business which German manufacturers have enjoyed for a long time.

The activity of the Friends is timed to a nicety because Congress is now considering emergency tariff legislation, and the Ways and Means Committee of the House is holding hearings on the various schedules of the tariff as a basis for formulating a new law. It is unnecessary for us to go into details of the matter at this time, for we have previously reported and supported the efforts of the chemical and allied industries to protect themselves from ruinous post-war competition and hold the strategic positions gained during the war. It is not Germany alone, but Japan and others, which loom as competitors against which the American industries cannot hold their own in free and unrestricted markets. Wherever these industries bear a vital relation to national welfare, we favor their reasonable protection.

A feature of the Bacharach bill, which passed the House at the last session of Congress and which was favorably reported by the Senate, is a repeal of the duty-free clause of the present tariff law which has long been a concession to our educational institutions. And rightly too, under past conditions. But sympathetic as we are with the financial needs of our schools, we cannot help feeling that they ought to stand on their own feet and pay the bill in order that vital American industries shall live. Most of the consumption by educational institutions is for student purposes, and the cost can be passed on to individuals. Hitherto we have published arguments urging that students should more nearly defray the actual cost of their education, and we support that plea in this instance.

Nor are we unmindful of the excellent arguments on the other side of the question, for of course there are two sides. Elsewhere we publish a communication from Prof. J. W. RICHARDS opposing our own view and supporting the retention of the duty-free privilege. It is but fair to say that Prof. RICHARDS is not alone in his stand, nor do we wish to connect him with the insidious and anonymous propaganda of the "Friends of Science, interested in its development." On the other hand he does not represent all of the colleges, for in the hearings before the Senate it was brought out through a questionnaire that the heads of chemical departments in seventeen out of twenty institutions favored the surrender of the duty-free privilege, even if about one-half of the scientific apparatus and instruments imported come in under the duty-free clause for educational institutions.

There is always room for an honest difference of opinion on questions of policy, and we welcome the frank expression of opinion from those who do not

attempt to conceal their identity. But propaganda is abroad in the land. Naturally it is camouflaged. It poses. It purports to be what it is not. It takes refuge in anonymity, which is the resort of those who have neither the courage of conviction nor pride of opinion. It pretends friendship and unselfish devotion while secretly advancing its own cause. It is rightly an object of suspicion and merits contempt. If the "Friends of Science, interested in its development," had come out into the open, they would at least have been credited with business acumen and integrity.

"I am afraid of the Greeks, even when they come bearing gifts."

Corporation Dividends, Education and Research

ON AUGUST 5 last at the general meeting in England of the corporation of Brunner, Mond & Co. a resolution was passed "that the directors be and they hereby are authorized to distribute to such universities or other scientific institutions in the United Kingdom as they may select for the furtherance of scientific education and research, the sum of £100,000 out of the investment surplus reserve account."

A stockholder named EVANS brought suit to restrain the directors from carrying out the resolution, on the ground that Brunner, Mond & Co. as a chemical manufacturer had no business with general science; that the resolution was *ultra vires*, and not within the objects of the company. Mr. Justice EVES in the Chancery Division of the High Court dismissed the complaint. For the purpose of this decision the distinguished magistrate did not discriminate between the powers of the company and its objects, on the ground that its charter permitted it to do all things incidental or conducive to its business as a chemical manufacturer. The evidence showed that it would benefit the community and also the corporation. The objection of the plaintiff that this was too vague was overruled. The directors and others on behalf of the corporation testified that the gift would tend to cause universities and institutions to train students and others whose services would be of benefit to the company. The company acknowledged itself in great difficulty to find the right class of men necessary for the conduct of its business as a chemical manufacturer, and his Lordship concluded that the advantage the corporation would gain by the better provision of properly trained men as a result of the aid thus rendered outweighed the objection raised by the plaintiff that some of the men trained by means of this gift might go to competitors.

A very pretty little scrap, we should say, with an unspoken touch of humor in it. We have plenty of just such persons here, who cannot see what chemistry has to do with selling soda ash. Of course dividends are dividends, and when they are earned and set aside for the purpose it would seem that the stockholders have rights in them. We note here a point in bookkeeping—that there may be a hazard in the expression "surplus available for dividends," and that the term "investment surplus reserve account" has greater merit. Research has become a function of industry, research in pure science, at all events, is a legitimate function of university procedure, and that industry needs pure science is shown by the fact that industry needs engineering, and engineering is the application of pure science.

From the record it may occur to some that it contains

a hint to the effect that in consideration of the gift, the several universities will train men especially for the alkali industry. We think it more likely, however, that this was allowed to be inferred from the testimony as an argument to win the case than as a statement of conditions. The establishment of Brunner, Mond & Co. is a great and progressive one, and as such its problems are doubtless very like those of great and progressive American organizations. And these are almost unanimous in calling, not for specially trained caustic men or soap boilers or pulp cooks or specialists of any sort, so much as for men whose training in science is broad and general and thorough; it wants men of scholarship in science rather than technicians. Courses in technology are of great value to develop the engineering sense of chemical engineers, but those institutions that give the best courses in this respect would be the last to offer them as a substitute for physics, for instance.

A point that cannot be evasized or made clear to the evans type of mind, or even demonstrated in court, or explained at a stockholders' meeting, is that it is better for a corporation if a competitor makes an advance in applied science than if neither of them makes an advance. In the former case the backward corporation is usually induced to shake a leg, as the saying is, and make an effort to keep up with the procession. The only way to do this is by means of research, even though it takes "surplus available for dividends" to pay for it. In the latter case—that is, if neither the corporation nor its competitor makes an advance—it is bad for the industry as a national institution. For a reason that those who are most to blame are inclined to call "psychological," the industry usually moves away to some other state or country.

Surveys of Chemical Industry

CHEMICAL industry and the Tariff Commission, as well as the Ways and Means Committee of the House of Representatives, are to be congratulated on the completion and publication of technical tariff information with respect to the chemical industry in a way that surpasses all previous effort. This information is presented in the form of reports known as "Tariff Information Surveys," dealing with all phases of tariff policy and tariff legislation now before Congress. They represent an unbiased summary of extended studies by the chemical staff of the Tariff Commission covering a description of each commodity, its uses, methods and processes of manufacture, differences in American and foreign practice, nature and source of raw materials used, data concerning production, import, export, prices and cost of production, and other pertinent facts. In other words, the series is a compendium of industrial chemical information of tremendous value, particularly in tariff revision but also as a general guide to each industry which has been surveyed.

Elsewhere in this issue are given details regarding the nineteen separate pamphlets in which are discussed all of the commodities covered by Schedule A of the tariff of 1913, which schedule relates to chemicals, oils and paints. Whether one is interested in citric acid, wood products, aluminum, chloroform or any other of more than two hundred commodities on which there is duty, or which are specifically mentioned in the "free list," he cannot afford to neglect this important source of reliable and comprehensive information.

Readers' Views and Comments

Duty-Free Apparatus for Colleges

To the Editor of Chemical & Metallurgical Engineering

SIR:—May I ask your indulgence for the presentation of a matter which I realize should appear in the *Journal of Industrial and Engineering Chemistry* but which I am prevented from publishing in that medium through the rather arbitrary action of its editor, Dr. Herty. I refer to a communication which I inserted in the November bulletin of the American Electrochemical Society in favor of duty-free importation of chemicals and laboratory apparatus for colleges and universities, and which was subsequently the subject of an editorial attack on me as secretary of the American Electrochemical Society in the December issue of the *Journal of Industrial and Engineering Chemistry*. When I attempted to reply publicly to the criticism the privilege was denied me on the technical ground that the editor had attacked me as secretary of an organization whereas I responded as an individual. I feel that there are two sides to the question and, with your permission, would like to present the point of view held by some in the colleges.

The Bacharach bill now before the Senate places an increased duty on chemical supplies and apparatus, and incidentally repeals the duty-free importation privilege now possessed by educational institutions. Many college professors, most of them members of the American Chemical Society, believe that such repeal will not only hurt the educational institutions by diminishing the purchasing power of their available funds, but will seriously hamper the efficiency of technical training and thus be detrimental to the progress of the country as a whole.

The argument for the repeal is based principally on the assertion that the enterprises manufacturing these articles are *key industries*, that it is of paramount importance that our country make what it needs in this line, and that in order to assist such industries it is necessary and advisable that the duty-free privilege be withdrawn from educational institutions. It is also stated that the use of foreign supplies and apparatus by our students is detrimental to their patriotism, giving them the idea that the U.S.A. is unable to compete in these things with foreign makers, and thus depressing their ideas of the resources and efficiency of their country.

It can be shown, however, that such repeal is neither advisable nor necessary, and for the following reasons:

1. Educating technical men is also to be classed among the *key industries*, in fact, it is *the master key*. Just as surely as "men are more than kings," just so surely is the efficiency of their technical training of greater importance than the extension of some of our other key industries. If any nation had ulterior designs upon our progress as a nation, which would hurt us most: to hinder our manufactures or to hamper the training and education of our technical men?

2. Duty-free importation was granted by our Government to increase the efficiency of education by increasing the purchasing power of available educational funds. It is certain that withdrawal of this privilege will decrease that purchasing power and therefore reduce the efficiency of the education given.

3. The great increase in industrial control laboratories and private and industrial research laboratories has certainly created a large demand for chemical and physical apparatus and supplies altogether apart from the educational institutions. Since the former cannot import duty free, they may be taxed by duties sufficient to keep our domestic industries going; the same tax on educational institutions would hamper their efficiency simply to make *more* business.

4. Many apparatus and supplies made abroad cannot be obtained in this country at all, being made only abroad. Why make the educational institutions pay a high duty on what is not to be had in this country? If the high duty falls only on the private laboratories, they will certainly look for a domestic source of supply, and thus those who are best able to bear the expense will assist in the establishment of new domestic industries.

5. The proposed repeal hits our allies as well as our former enemies. We get apparatus and supplies from England and France, and it seems unfortunate, to say the least, that we treat friend and foe alike.

6. Concerning the effect on the students' patriotism, I wish to take exactly the opposite stand from that expressed by those favoring repeal of the duty-free privilege. College and university should teach students the truth, and if foreign apparatus and supplies are better or cheaper (duty-free) than the domestic, the students should know it; the last thing to teach them is a blind pseudo-patriotism which thinks that anything American is necessarily the best to be had or is "good enough." Moreover the student who has any red blood in him (and most of them have) will feel a generous ambition to outdo the foreigner when he learns the facts. My experience in teaching university students for over thirty years leads me to state without hesitation that knowledge of the facts stimulates the men by putting a goal of achievement before them, and engenders in them the praiseworthy ambition to try to beat the foreigner.

7. Finally, for purely pedagogic and efficiency reasons, teaching equipment should be the very best obtainable, irrespective of its source. If I wish to show a student of qualitative analysis the reaction of potassium, it is of first importance that I use the purest potassium salt I can get (and am able to buy) irrespective of its source. If I want to show my students the spectra of the elements, I should have the best spectroscopic my funds will procure, irrespective of who makes it, in order to raise my teaching to its highest efficiency.

When it comes to education and training of our technical men, we can very well afford to use foreign materials from any source when by so doing we can thereby increase the efficiency of the education given, and thereby eventually acquire the ability to beat the foreigner at his own business. Any other principle will result in hampering technical education, and thereby defeating the very ends that we wish to accomplish. I plead for a broader vision and for a further look ahead.

Hearings on Patent Office Bill

Conference Committee Reopens Hearings on Bill for Relief of the Patent Office in Order to Give Opponents of Section 9 Opportunity to Register Their Objections

AS ANNOUNCED in our issue for Dec. 29, 1920, the joint conference committee of the House and Senate on the Patent Office bill reopened hearings on that measure and listened to a large number of witnesses on Jan. 5 and 6. In convening the session Senator Norris, presiding, called attention to the extraordinary nature of the proceedings—holding hearings on a measure which had passed both houses of Congress and which had been referred to conferees for adjustment of differences. He explained that the committee could listen to arguments bearing on only those matters on which the House and Senate were in disagreement. These were particularly the matter of salaries and clerical force in the Patent Office, and section 9, relating to the patenting by the Government of the inventions of its employees and assignment of such patents to the Federal Trade Commission for administration through license.

SALARY REDUCTIONS INSERTED BY SENATE

H. R. 11984, as passed by the House for the relief of the Patent Office by increasing the salaries of employees and increasing their number, was amended by the Senate reducing the salary recommendations of the House and reducing the force of employees. As brought out in the testimony, the effect of the bill would be to reduce the force 15 per cent at a time when the work of the office has increased 30 per cent. It was also shown without difficulty that salaries in this important bureau of the Government were woefully inadequate, being very much lower than those paid in private industry for similar service, as well as being incommensurate with the education and technical ability required of Patent Office employees. Testimony was introduced by former Patent Commissioner Ewing to show that the Patent Office had been steadily disintegrating for the past thirty years, due to failure to provide salaries that would hold competent men. He explained that the patent system of the United States requires examiners who are not only skilled in patent law but whose familiarity with conditions in the Patent Office is essential to the expedition of business. Deterioration of the force, through loss of examiners by resignation, not only retards prompt attention to applications but makes it impossible to give to applicants the careful consideration necessary to avoid the issuance of invalid patents. Mr. Ewing stated emphatically that unless prompt relief were granted the Patent Office would be congested with a volume of work that could not be transacted, and industry would suffer.

NECESSITY FOR INCREASING SALARIES URGED

Among others who testified regarding the inadequacy of the present salaries, or even those contemplated by the Senate amendments, was E. J. Prindle, who stated that resignations in the Patent Office were continuing in spite of the fact that the present bill promised some relief. He cited these resignations as evidence that the prospect of receiving the lower salaries recommended

by the Senate was not sufficiently attractive to hold men in their positions, and he urged the restoration of the salaries recommended by the House. Mr. Prindle offered resolutions passed by the National Research Council, Engineering Council, American Chemical Society and National Association of Manufacturers supporting the necessity for relief in the Patent Office. He also introduced some results of a questionnaire of the American Patent Law Association, showing that former examiners in the Patent Office are now receiving from private industry salaries several times as great as they received in the Government service. Practically all of the witnesses before the committee, including those who appeared for other reasons, indorsed heartily the necessity for increasing salaries in the Patent Office and providing a force adequate to cope with the business of that bureau.

HOUSE PROVISION LIKELY TO BE REINSTATED

In explanation of the Senate's amendment reducing salaries it should be stated that the Senate is not unalterably committed to that program, nor does it necessarily believe that the House provisions were too high. It was felt that the subject of salaries should receive the attention of the Senate conferees, and the best way to do that was to introduce amendments. Senator Norris stated in the hearings that the two committees were not in material disagreement on this point, from which it may be inferred that the contentions of the witnesses will prevail and that the House provisions will be reinstated after they have been reviewed.

OPPOSITION TO SECTION 9

Opponents of section 9, which the Senate attached as a rider to H. R. 11984, appeared before the committee in large number, representing chemical manufacturers and industrial companies. The arguments were mainly a repetition of those published in *CHEMICAL & METALLURGICAL ENGINEERING* of Oct. 27, 1920, following a meeting of several scientific societies in New York before which Dr. Cottrell and Dr. Alsberg spoke in behalf of the measure. Practically all of the witnesses opposing this section of the bill not only objected to it in principle but felt that it should not be attached to the bill for relief in the Patent Office. They advocated its elimination and separate consideration.

The gist of the opposition to section 9, as expressed before the committee, is that it will bring the Government into competition with private industry; that the Federal Trade Commission as the administrative agency has not the confidence of the country; that the granting of licenses involves the question of discrimination among competitors in an industry; that the Federal Trade Commission would be under the necessity of defending title to its patents for the benefit of its licensees; that dedication of a patent to the public meets satisfactorily the condition which section 9 proposes to relieve; that if Government research is con-

ducted in the proper sphere of fundamental science or in those industries for which there is no established research agency no need will exist for section 9; that if Government research is not so conducted it will extend into development work that will involve large expenditures; that more extensive industrial research by the Government will discourage private industry from extending its research activities and rely more and more on the Government for the solution of its problems; and that no special machinery is required to meet the situation as stated by proponents of the measure.

ADMINISTRATION UNDER PROPOSED SYSTEM QUESTIONED

The possibility of administering satisfactorily patents assigned to the Federal Trade Commission was the subject of much of the testimony and of colloquies between members of the committee and witnesses. It was contended by the latter that the licensing of patents would be the cause of much dissatisfaction to the inventor and the industry and the public. Frederick P. Fish stated emphatically that the Federal Trade Commission would find itself confronted with the necessity of choosing between exclusive and non-exclusive licenses; that if the former were adopted there would be dissatisfaction among unsuccessful applicants and the Commission would find itself open to the charge of favoritism. When Senator Norris said that he doubted if much hue and cry would be raised by the granting of an exclusive license Senator Brandegee retorted, "Let the Commission grant an exclusive license to the Standard Oil Co. and see what will be said." In Mr. Fish's opinion this feature would open the way for a vast amount of dissatisfaction if not scandal. If the Commission should grant non-exclusive licenses it would seem unlikely that any would be taken, in which event nothing more would be accomplished by the bill than by original dedication to the public.

LIMITATION OF GOVERNMENT ACTIVITY URGED

On the contention that dedication to the public is now satisfactorily meeting the situation R. P. Perry, of The Barrett Co., introduced some evidence based on the premise that "industry, inventors and the large majority of the American public believes that governmental activities should be limited to those fields where private industry cannot function as well and that private enterprise should be encouraged in all fields where it can function as well as or better than the Government."

Continuing, Mr. Perry said: "Now what does this mean in the present case? It means simply this, that the proper and legitimate sphere for Government technical research is, in the opinion of industry, limited to such work as formulating standards of quality in fields of general public interest (drugs, foods, etc.), developing testing methods and determining accurate fundamental data, such as the true physical constants of materials and making investigations in fields of agriculture and animal industry not reached by private enterprise. It means that Government technical research is out of bounds when it goes into the development of new products or processes in chemical or other applied industry. The legitimate need to be met is therefore, in my opinion, a limited need and if the Government keeps within its proper sphere it will only very occasionally and incidentally develop any patentable inventions relating to applied industry and consequently will very seldom have occasion to take out patents. I cannot conceive of it other than as a very limited need

unless Government technical research unconsciously or consciously is to invade the fields of private enterprise in competition with industry. . . . I believe such invasion will sooner or later be the inevitable result of the plan proposed by section 9. At the present moment the point is that unless there is to be such expansion of effort into the field of private industry the needs to be met are limited and the present arrangement has met these needs."

By way of proof that under present conditions Government inventions are exploited by the public when open to public use Mr. Perry cited the instances of calcium arsenate, which was developed by the Bureau of Chemistry as an insecticide; oil- and water-proofing in concrete, developed in the Office of Public Roads; hog cholera serum, a product of the Bureau of Chemistry; and phthalic anhydride, developed in the Color Laboratory.

ANOTHER OBJECTION TO SECTION 9

An objection raised by Mr. Perry and others to the present innovation embodied in section 9 is that it will be an entering wedge that will not stop with the patenting of inventions made by Government employees in the course of their official duties, but that since an undeveloped invention is worth little or nothing there will be a great temptation to develop patents so that they will be of some value to the inventor and the Federal Trade Commission. Indeed, it was the contention of witnesses that undeveloped patents would find little or no sale, and that development would be essential if the plan of section 9 were to amount to anything and meet the expectations of its sponsors.

The prospective expense to the taxpayers entailed by this experiment in patent administration was the subject of attack by witnesses. Mr. Randall, secretary of the Air Reduction Co., foresaw the necessity for the Federal Trade Commission building up within itself an organization for the expert administration of patents, defending infringement suits, etc. Senator Norris asked why it would be necessary for the Federal Trade Commission to defend patent suits. He was informed that prospective licensees would not accept a license, especially if non-exclusive, if there was a prospect that they would have to prosecute infringers or stand suit for infringement in case their patent should prove invalid. The situation would be little better in the case of exclusive licenses, and in any event it would be incumbent on the Federal Trade Commission to maintain an elaborate legal department.

An interesting witness was former Commissioner of Patents Ewing. Speaking from some years of experience he expressed opinions on various points brought out by other witnesses. In his judgment it would be necessary to issue exclusive licenses if the scheme were to have any chance of success, and yet he felt that there was so much objection to that kind of discrimination that it would kill what little chance of success there might be for section 9 to function as its sponsors hope. In Mr. Ewing's opinion the whole matter would not amount to anything, because it would not work practically. He was certain that the Government would have to protect its licensees by defending patent suits.

A. I. C. E. OPPOSES SECTION 9

David Wesson presented the attitude of the American Institute of Chemical Engineers as follows:

The Institute has an able committee on patent legis-

lation which reports at the regular semi-annual meetings progress of all patent legislation.

The Nolan bill, as originally passed in the House, was discussed by the Institute in open meeting and approved.

When section 9 was added to the bill the Institute, in conjunction with the New York sections of the American Chemical Society, the Electrochemical Society and the Society of Chemical Industry, held a special meeting in October last in New York at which Dr. Cottrell and Dr. Alsberg fully explained the intent and meaning of section 9.

The meeting, representative of the industrial, scientific thought of the country, discussed the proposition, which was disapproved by all who spoke on the subject.

The patent committee of the Institute reported the bill at the annual meeting held in New Orleans Dec. 6, 1920. The following resolution was drawn up and unanimously adopted:

Be It Hereby Resolved, That Congress be petitioned to pass Bill H.R. 11,984, otherwise known as the Nolan bill, in its original form, without the addition of section 9, that the Patent Office may obtain the needed relief to maintain its efficiency; and be it further

Resolved, That we consider the passage of section 9 would lead to the interference by the Government bureaus with business enterprises with which they were originally designed to co-operate in supplying service and benefit to all.

RUST MEMORANDUM ON SECTION 9

Mr. Randall asked the committee to divorce section 9 from the bill in anticipation of the substitution therefor of an act to be drawn by co-operative effort of all the parties at interest. He summarized the hearing with the following wire from H. B. Rust, president of the Koppers Co.:

The principal purpose of our patent system is to encourage private enterprise and invention. This section will do exactly the opposite.

1. It will place a body of Government-owned and administered patents, worked out by Government inventors at public expense, in competition with another body of patents developed and owned by private industry. Such an effect is bound to be discouraging and harmful to all industry.

2. It will make it possible for executive orders to direct that all patents taken out in any Government bureau be turned over to the Federal Trade Commission for administration.

3. It will make the Federal Trade Commission a holding agency for a great group of patents affecting practically every branch of private industry.

4. It will make it possible for the Federal Trade Commission to discriminate in the issuance of licenses, allowing them to certain parties and refusing them to others.

5. It will even make it necessary for the Federal Trade Commission to so discriminate, "for unless licenses are restricted in number there is no gain over dedication of the patent to the public in the first instance."¹

6. It will make it possible for a taxpayer of the United States to be refused the right to use an invention that he has contributed funds to develop.

7. It will involve private industry in continual litigation with the Government on questions of patent validity, infringement, etc., litigation that will become a burden not only to the parties, but to the public.

8. It will discourage the co-operation between Government bureaus and private concerns that is now benefiting both. Private industry will certainly not be willing to give Government employees information that may later be developed into patents and turned against it.

9. It will place any Government bureau developing patents in an unfair position with respect to related

industries in competition. The Government bureau has means, not possessed by any private individual, of acquiring information from competitors. Such information can and will be used in the development of patents and to the detriment of competing industries.

10. It will give undue personal benefit to the Government employee working with the advantage of Government funds and Government information.

11. It will give undue personal benefit to a favored group of Government employees who happen to be so placed that they can work on inventions, as compared with the many other employees who are not so placed.

12. It will place an irresistible temptation before Government employees, especially of the technical and scientific groups, to devote their time to work on patentable inventions that will lead to personal benefit to themselves.

13. It will create dissatisfaction among those employees who are not permitted to work on inventions.

14. It will seriously curtail the fundamental technical and scientific activities of various Government agencies that have few patentable possibilities, but are, nevertheless, of the utmost value to industry.

15. Under the patent law of the United States, inventions, made by an employee at his employer's expense, belong to the employer. The employer of every Government employee is the public. Inventions of Government employees are made at the expense of the public and should belong to the public without any qualification such as this section 9 introduces.

The conference committee of the House and Senate is respectfully urged to reject this section.

DR. COTTRELL SPEAKS FOR THE SECTION

Dr. Frederick G. Cottrell, late Director of the Bureau of Mines and new chairman of the Division of Chemistry and Chemical Technology of the National Research Council, appeared in behalf of section 9. Dr. Cottrell is generally recognized as principal sponsor of the bill. He explained to the committee that this is an experiment in administration of patents in the interest of the public; that in the course of official duties Government employees produce as a byproduct certain patentable discoveries which, unless patented and administered, will be lost to public use; that dedication to the public does not, in his opinion, meet the situation; and that the bill has been drafted as a permissive measure to try the experiment of assignment to a public body and administration by it. In the course of his testimony Dr. Cottrell was questioned by a representative of the Standard Oil Co., who asked, in effect, "Would the industrial concerns with which the various Government bureaus now have co-operative agreements allow Government employees to enter their works and laboratories if they suspected that later they might be asked to pay a royalty on some invention made as a result of knowledge and information picked up in the course of co-operative relations?" Dr. Cottrell was of the opinion that the operation of section 9 would not affect the cordial relations now existing between Government bureaus and various industrial concerns. He spoke from some years of experience in administration of Government technical work, and said that in his judgment there was great need of some such medium as section 9 in order to salvage and make available for public use many discoveries now lost. At the present time there are a number of such patented discoveries awaiting the establishment of a suitable agency through which the patents can be assigned and licensed. In reply to the criticism that the Federal Trade Commission would experience a great deal of difficulty in licensing patents Dr. Cottrell cited the fact that during the war that body administered a number of enemy-owned patents, licensing their use without difficulty.

¹Quotation from CHEM. & MET., Oct. 27, 1920.

Bacteria as Chemical Reagents

Activities of Micro-Organisms—Factors Determining the Extent of Chemical Transformations
by Bacteria—Food for Bacteria and Its Influence on Their Activities—
Bacterial Standards of Purity—Chemical Equation of Life

By ARTHUR I. KENDALL

AT THE very foot of the ladder of life, the simplest in structure and the smallest in size, there is a group of micro-organisms known as bacteria. The sinister impressions which arise at the mere mention of germs, indeed all the notoriety which attaches to the term "bacteria," arise from the malignant potency of a small but formidable group of these micro-organisms—the pathogenic microbes—whose activities are in opposition or partial opposition to those of plants, animals or man.

In reality the prime function of bacteria in nature is one of beneficence. Without their participation in the rotation of certain elements between the living and the dead all life would inevitably cease upon this planet. Bacteria maintain a balance between the organized and unorganized kingdoms in nature. They restore those essential elements, of which the available supply is limited, to the soil in fully oxidized form, suitable for resynthesis by plants through the agency of sunlight acting upon chlorophyll. Otherwise much nitrogen and other elements essential to the perpetuation of life would be locked up in complex, useless combinations in the dead bodies of plants and animals and their waste products, while vestiges of the slowly weathering corpses of prehistoric monsters and prehistoric vegetation would still encumber the earth.

ACTIVITIES OF MICRO-ORGANISMS

The purification of water and sewage by bacterial action is illustrative of their analytical activation. The soluble organic substances of sewage and contaminated water are broken into simpler hydrolytic products through the action of soluble digestive enzymes which the bacteria secrete, and in turn these relatively simple compounds are absorbed, digested and excreted by microbes as fully oxidized derivatives of nitrogen, carbon, etc. Such compounds are available for plant synthesis. The biological purification of water and sewage, therefore, is essentially a process of bacterial digestion. The rapidity with which the biological purification of water and sewage takes place in specially constructed filters is illustrative of the advantage of creating favorable conditions which thus hasten the natural process. It also indicates the great measure of chemical transformation which these very small microbes bring about.

In addition to the great analytical processes of the nitrogen cycle, which are caused by bacteria, the artificial and natural souring of milk, of ensilage and many other preservative processes are the work of microbes. The fermentation industries for the production of organic acids, alcohols and many patented reactions, and a multitude of others, all indicate uses to which the intelligently controlled activities of micro-organisms can be applied.

Micro-organisms play an important part in the human

economy. The ravages of tuberculosis, typhoid, cholera, dysentery, diphtheria and other infections are well known, but the normal bacteria of the alimentary canal also exercise a protective function against invasion by them. The extent to which this protection shields the host against contagion is not yet known, but unquestioned evidence exists in favor of it. Modern research is leading to the formation of dietary measures which will increase this protection, or re-establish it, if it has been diminished or lost.

Bacteria are minute, unicellular organisms, devoid of sex, and their reproduction is a simple and rapid process. They are also devoid of any catalytic pigment, as chlorophyll, so that it would appear to be impossible for bacteria to become synthetic agents, as are the green plants. Bacteria require preformed food in their dietary; hence their activities are essentially analytical rather than synthetic. The perpetuation of bacteria requires an expenditure of energy, and the source of this energy, as will be shown, is of leading importance.

FACTORS DETERMINING THE EXTENT OF CHEMICAL TRANSFORMATIONS BY BACTERIA

The simplicity of structure of bacteria and absence of any photochemical agent, such as chlorophyll, within them automatically reduce their activities to two closely related but very distinct processes. These are, first, an anabolic, or structural, process or phase, and, secondly, a vegetative energy, or katabolic phase. The former perpetuates the integrity of the species, the latter determines the function of the organism.

Now it is just because the individual bacteria are so small that their activities are so great. The physical basis for this resides in the large ratio of surface of the organism to its volume or weight, and also to the rapidity with which successive generations of bacteria appear when conditions are favorable to their growth.

The cholera vibrio, for example, measures about 2 microns in length and 1 micron in diameter. The volume, therefore, of a single cholera germ is about 0.000000002 cu.mm., while its surface measures nearly 0.00001 sq.mm. For purposes of comparison it may be stated that a man weighing 100 kg., 200 cm. in height, has a surface area of approximately 2.4 sq.m.

Since the energy requirement of living things varies with the surface area rather than the volume or weight, it is evident that the relatively large surface area of bacteria in proportion to their volume or weight creates a condition requiring proportionately a great deal of energy to maintain them. It should be borne in mind, however, that the energy requirement of bacteria, measured in terms of chemical transformation, depends somewhat on the type. Thus, bacteria which play a prominent part in natural processes appear to effect chemical transformations of even greater magnitude than those of

similar size which are pathogenic for man. The second factor which plays an important part in determining the extent of chemical transformation by bacteria is the amazing rate of reproduction. Under favorable conditions successive generations of cholera vibrios may appear at intervals as frequent as every fifteen minutes, each individual dividing into two individuals in this short time. The theoretical descendants of a single vibrio, therefore, in four hours would number about 32,000. The weight of the progeny would be approximately 0.00064 mg., while the combined surface of the descendants of a single organism at this time would be nearly 0.32 sq.mm. The energy requirement of a four-hour culture, therefore, would have increased 32,000 times, but the actual amount of material necessary to build up the bodies of the microbes at this time would be only 0.00066 mg. in weight. Fortunately such a rate of reproduction cannot long be maintained. Nature provides barriers and restraints, and these always keep proliferation within endurable limits. Were this not so man and animals would long ago have perished.

ESSENTIAL FOOD FOR BACTERIA

Bacteria, in common with all known living entities, contain nitrogen as an essential element in their structure. Now nitrogen is notoriously an inert element, and this inertia is perhaps a feature of stability in the changing manifestations of protoplasm. Nitrogen is therefore necessary for the structure of all bacteria, and reproduction and growth are impossible in environments which do not contain it in utilizable form.

The nature of the nutritional compounds containing nitrogen required by bacteria is varied. Some types appear to use simple combinations of nitrogen with hydrogen, carbon and oxygen. The great majority of micro-organisms can derive their nitrogen requirement from amino acids or relatively simple polypeptids. Some—as the fastidious *gonococcus*—require practically unaltered protein from human sources for their cultivation.

Nitrogen, although essential for the structural requirements of bacteria, is without apparent value as a source of energy. This is true for animals and man as well. Indeed, when appropriate nitrogenous compounds, as protein or protein derivatives, are the sole source of dietary energy for bacteria, animals or man the carbon of the protein or its derivative is oxidized for this purpose only after the nitrogen is removed from the molecule by a process of deamination. The ammonia resulting therefrom is left unchanged, or transformed to urea and excreted in this form.

Dietary energy for bacteria and for animals arises from the intracellular oxidization of carbon, so far as we can judge from available evidence. It is also generally true that the partly oxidized carbon existing in carbohydrates is more readily utilized than the reduced carbon of the amino acids, for the same purpose.

The waste products arising from the utilization for energy of such nitrogenous substances as amino acids, polypeptids or proteins, furthermore, are, as we have indicated above, strikingly different from those derived from the intracellular combustion of carbohydrates. A few examples will illustrate the immense importance of this difference.

INFLUENCE OF THE CULTURE MEDIUM ON THE ACTIVITY OF THE BACTERIA

One of the leading culture mediums for bacterial cultivation is called "plain" or sugar-free broth. It con-

sists essentially of a sterile aqueous solution of 1 per cent of peptone and 0.3 per cent meat extracts, all neutral in reaction. This medium offers amino acids and polypeptids as the sole sources of nitrogen, carbon and other elements essential for bacterial growth. In such a medium, therefore, both the structural and energy requirements of bacteria must be obtained from amino acids, or combinations of amino acids, which are not coagulated by heat.

An entirely similar medium, both in composition and reaction, but containing about 1 per cent of glucose, is designated "glucose broth." Both plain and glucose broth offer to bacteria amino acid complexes for structure. But in plain broth these same amino acids are also the sole sources of carbon for the energy requirement of the bacteria, whereas in glucose broth a choice is available between the nitrogen-containing carbon complexes—i.e., amino acids and their derivatives—and the non-nitrogenous carbohydrates for the energy requirements of the microbes.

The diphtheria bacillus is an organism whose formidableness to man is measured by the potency of the water-soluble, extracellular toxin it produces. Under certain conditions 0.025 c.c. of a seven-day *plain* broth culture of this organism will kill a guinea pig weighing 250 g. within four days with definite symptoms and lesions.

In other words, in the plain broth, in which carbohydrates are lacking, the energy requirement as well as the structural requirement of the diphtheria bacillus is derived from the utilization of protein derivatives, and under this condition a very powerful specific soluble poison is produced which is the deadly weapon of the diphtheria bacillus. The same diphtheria bacillus, however, grown in the same medium but to which a small amount of glucose is added, produces substances which are not even slightly poisonous; they are, in fact, potentially buttermilk. Instead of producing the virulent poison they secrete essentially lactic and acetic acids.

The diphtheria bacillus, therefore, under the conditions of culture stated above, is a veritable Dr. Jekyll and Mr. Hyde. Grown in a purely protein medium it produces a virulent poison; in a glucose-protein medium it forms potentially buttermilk. The utilization of glucose in place of the nitrogenous amino acid complexes for energy is the only known factor concerned in this remarkable transformation.

The colon bacillus, a common inhabitant of the intestinal tracts of man and of animals, produces considerable amounts of indol from the utilization of tryptophan, an important amino acid, when protein derivatives are the only available sources of energy. When a utilizable sugar—as glucose—is added to the medium the products arising from the growth of the organism fail to include indol. They are, on the contrary, principally lactic and acetic acids. [It would appear from this that glucose might occasionally be used advantageously to avoid the evil odors attendant on putrefaction.—ED.]

The bacteria which incite typhoid fever, bacillary dysentery, cholera and many other diseases react in a precisely similar manner; they produce characteristic nitrogenous products, which appear to be specific for each organism, all nitrogen-containing, when protein or protein derivatives only are available for energy. All of these formidable incitants of human infection, however, produce the chemical equivalent of buttermilk when an available source of energy in the form of carbohydrate is present in mediums where they are growing. Generally speaking, the carbohydrate spares the protein constitu-

ents of the nutritive environment from decomposition for the energy requirements of the organism.

IMPORTANCE OF THE UTILIZATION OF PROTEIN AND CARBOHYDRATE FOR ENERGY

It is obvious, therefore, that in either medium protein must be used for the structural requirement of the organisms, and it is also evident that the products arising either from the utilization of protein or from that of carbohydrate for *energy* should be of great significance in defining the function of the various kinds of bacteria. This is emphasized by the far greater requirement of bacteria for energy than for structure.

This great fundamental principle of the use by bacteria of either carbohydrate or protein for energy is in all probability the most important single principle to note in approaching the unexplored field of the chemistry of medical, agricultural and industrial bacteriology.

An illustration or two will be explanatory.

Many years ago at the Lawrence Experiment Station at Lawrence, Mass., bacterial sewage filters which had nitrified the organic constituents of sewage successfully for a period of years were found to permit the passage of the nitrogenous constituents of sewage but little changed in terms of free and albuminoid ammonia when cane sugar was added to the sewage just before it was introduced to the top of the filter. An explanation was not available when this experiment, repeated several times, was performed. In all probability this is a concrete example of the sparing action of carbohydrates for proteins in fermentation. If it is easier for the bacteria resident in the filter to obtain their energy from cane sugar than from the nitrogenous constituents of the sewage they will do this very thing, and the effluent will show theoretically but little chemical evidence of nitrification.

Several years ago certain eggs, broken and mixed with a considerable amount of cane sugar, were seized and condemned on the ground that they were filthy, rotten and decomposed. There were many thousands of colon bacilli per gram of egg, and it is known that *Bacillus coli* produces relatively large amounts of indol, an exceedingly foul-smelling substance, from the decomposition of protein.

Most careful analysis confirmed the high bacterial content of these eggs, but failed to reveal ammonia, indol or other products indicative or even suggestive of protein decomposition by *Bacillus coli*. The reaction of the eggs, contrary to what might have been expected from protein putrefaction, was distinctly acid, and lactic acid in considerable amounts was found in the mixture. These eggs, furthermore, were used in cakes and other culinary products without the slightest suggestion of disagreeable odor or taste. What appears to have happened is readily explained—the colon bacilli derived their energy requirement from the cane sugar, leaving the protein of the egg practically untouched except for the minimal amounts necessary to fulfill their nitrogen structural requirement. Evidence of protein decomposition would scarcely be expected under the circumstances, and in reality the principal change was at the expense of the cane sugar, rather than the protein.

Nature's method of preserving milk by souring, so extensively practiced in the tropical and subtropical Orient, especially by nomadic peoples, and the recently developed use of bacteria for "starters" in the butter industry are examples of the selective action of bacteria

upon sugars in place of the protein constituents. The development of acid tends to retard, or even prevent, the growth of non-lactose-fermenting proteolytic bacteria which otherwise might induce putrefaction in place of souring. Examples might be cited almost without limit upon this phase of the problem, but another phase deserves mention because of the theoretical possibilities associated with it.

SIGNIFICANCE OF "UTILIZABLE CARBOHYDRATE"

For many years, beginning with 1885, bacteriologists have added various sugars, starches and glucosides to plain broth, and have observed that specific bacteria differ in their respective powers to "ferment" or "not ferment" the various carbohydrates. Long-continued observation has led to the selection of a few sugars for general bacterial use, the kinds depending somewhat upon the organisms studied. Thus glucose, lactose, saccharose and the alcohol mannitol have been found by repeated trials to be of great use in separating bacteria derived from the alimentary canal into distinct types or species. Confirmatory tests, using the serums of horses immunized to certain of the respective pathogenic types, have been employed in the final diagnosis of these.

Although the empirical facts relating to the respective availability of such carbohydrates have been thus laboriously established, the underlying principle appears to have been overlooked. This principle is that in the presence of such utilizable carbohydrates they are consumed by the bacteria for their energy requirement, while the protein constituents of the medium are spared. The recognition of the principle of this *sparing action* of utilizable carbohydrate leads at once to a contemplation of the most fundamental consideration of all—what relationship exists between the structure of a utilizable carbohydrate and the ability of the living protoplasm of a specific organism to use such a structure as a source of energy? Some of the relationships between the stereo configuration of very closely related sugars and their respective values as sources of bacterial energy are truly amazing in their specificity. Bacteria are extraordinarily delicate appraisers of optical antipodes; that is, they are themselves sensitive polariscopes.

D-glucose, *d*-mannose and *d*-fructose differ, according to available information, solely in the arrangement of hydrogen and hydroxyl around the carbon atom next to the aldehyde group—except in fructose, which is, of course, a ketone. The brilliant researches of Emil Fischer and others have shown the specific arrangement of the six carbon, twelve hydrogen and six oxygen atoms which collectively determines the identity of each member of this group, which tends to form a dynamic chemical equilibrium of the three through a common *enol* when any one of them is dissolved in an alkaline aqueous solution.

Furthermore it will be seen from the diagram that

d-glucose and *d*-mannose differ from each other solely in the arrangement of the H and OH groups next to the aldehyde group. This difference consists merely of a reversal of the two in mannose as compared with glucose. Neither the number nor the kind of groups of atoms differs; it is merely a transposition of one H and one OH upon one carbon atom out of the six. The remaining carbon atoms and associated groups are precisely the same. Yet certain bacteria, as *Bacillus proteus*, and cholera vibrios can derive energy from the intracellular utilization of glucose, but appear unable to utilize mannose in the slightest degree. On the contrary, bacteria which are apparently much more fastidious in many of their dietary requirements, especially with reference to protein, can ferment mannose as well as glucose. Observations with several hundred bacteria, comprising many of the more important pathogenic types, have revealed similar instances of a most extraordinary relationship between the structural configuration of various carbohydrates and their susceptibility or immunity to specific bacterial decomposition. Apparently definite strains of bacteria never make a mistake in picking out the proper structural formula for transformation into energy. Thus two strains of cholera and proteus, tested at intervals of four years, have consistently used glucose and refused mannose, as stated above. Whether all strains of cholera or of proteus, for example, that are in existence at the present time would be unable to utilize mannose cannot be decided in the light of available information. Conversely, if strains said to be one or the other of these types are found which ferment mannose, an extremely fundamental question of their respective identities would at once be raised.

Observations upon one hundred different strains of dysentery bacilli have revealed one small group of three which do not ferment galactose. They do ferment (as do all the remaining types which could utilize galactose) glucose, mannose and fructose, as well as other sugars.

So far as available evidence goes, the alcohol *d*-arabitol is fermented only by members of the *Mucosus capsulatus* group. If a large series of authentic strains of this group exhibit in common this peculiarity, a means of rapid diagnosis for one group will have been demonstrated. The application of this principle along the line of specific bacterial diagnosis is perfectly obvious.

BACTERIAL STANDARDS OF PURITY

The unerring, uncanny positiveness with which the two cholera and two proteus organisms distinguish between glucose and mannose suggests at once a means of detection of traces of the former sugar as an impurity in the latter. The extension of this principle to possible bacterial standards of purity for all sugars and indeed for many other substances through a careful selection of particular bacterial strains for specific purposes needs no further elucidation.

As an example of the possible delicacy of such a reaction mention may be made of the common use by bacteriologists of milk containing litmus as an indicator. Milk as ordinarily purchased and used in bacteriology contains about 3 per cent of protein, 3 per cent of fat, and 5 or more per cent of carbohydrate in addition to inorganic salts and water. Clearly, bacteria have a theoretical choice of protein or carbohydrate for energy. Fats are omitted for the sake of simplicity

from this discussion. The carbohydrate content of milk consists of somewhat less than 0.1 per cent of glucose, the remainder being lactose.

Dysentery bacilli and many others can ferment glucose but not lactose. Bearing in mind what has been said, it is obvious that the theory outlined demands a primary bacterial attack upon the glucose for energy. If this is used up without the formation of products inimical to the further growth of the bacteria they must subsequently derive their energy from the protein constituents of the milk, because experience has shown that dysentery bacilli cannot attack the lactose.

The products of the fermentation of glucose by dysentery bacilli are acid; those arising from the putrefaction of the milk proteins are alkaline. The litmus indicator shows this sequence very clearly. It responds to the acidity generated from less than 0.1 per cent of glucose by turning distinctly violet, then it gradually becomes blue as the alkaline products of protein decomposition for energy accumulate and neutralize the fermentation acid.

This is a crude illustration of the ability of specific bacteria to distinguish very small amounts of a specific carbohydrate in the presence of another. Even with the relatively gross conditions of this experiment the results are unmistakable. How delicate such a reaction can be made is yet undetermined. The application of this principle to the identification of minute amounts of specific sugars and to the products of hydrolysis of bioses and polysaccharides is perfectly clear.

Attempts to produce bacterial evidence of enolization and subsequent equilibrium of hexoses (as of the glucose-fructose-mannose group) in alkaline media have so far been unsuccessful, although the prevailing idea regarding this phenomenon should be susceptible of demonstration.

CHEMICAL EQUATION OF LIFE

However interesting, instructive or important the relationships between structure of carbohydrates and their adaptability for energy may be as abstract phenomena, there is underlying all these manifestations the problem of the chemical equation of life. The remarkable precision with which bacteria of certain types distinguish between such closely related hexoses as glucose and mannose has its exact counterpart in the equally astonishing phenomena of specific immunity and susceptibility of animals and man to bacterial infection.

Man is relatively free from many of the epizootic diseases of animals, and animals do not naturally become infected with many human infections, as typhoid fever. Much more specific examples of immunity and susceptibility to infection are known, however. Algerian sheep are said to be immune to anthrax, that bacterial pestilence which has decimated herds of ordinary sheep both in Europe and America. House mice are extremely resistant to infection with glanders, while field mice are unusually susceptible. Goats are not readily infected with tubercle bacilli, but cattle and swine are extremely prone to the disease.

Science is wholly uninformed with respect to the origin and mode of the action of immune processes. Much empirical knowledge has been laboriously collected concerning the methods of testing such immunological phenomena, but an adequate, satisfying explanation of them is wholly and entirely lacking.

At first sight the enormous complexity of proteins to which immunological processes are ordinarily ascribed

would appear to be an insurmountable barrier to further advances. Seventeen amino acids which comprise the building blocks of the proteins may be arranged in hundreds of thousands of combinations within a molecule as large as that of a native protein. Realizing what a mere transposition of H and OH in glucose does in creating bacterial immunity, the enormous complexity of the extension of this process to protein and protoplasmic sources is very obvious.

Nevertheless, bacteria may throw some light even here. *Bacillus coli* and *Bacillus proteus* and some others are tryptophanophilic; in the absence of non-nitrogenous sources of energy they appear to pick out tryptophan from the protein molecules and utilize the alanin portion, leaving indol as a useless residuum. Other bacteria select other amino acids. Without prolonging this suggestion and without mentioning some other features of bacteria decomposition of protein which are pertinent, it may be stated that untouched possibilities remain which the bacteriological chemist of the future will study and from which he will glean information leading directly to the heart of that mystery of mysteries, the chemical equation of life.

Use of Bituminous Coal as Water-Gas Generator Fuel*

BY W. W. ODELL†

IT HAS long been recognized that coke is a more desirable fuel than bituminous coal in water-gas apparatus of present design, but still considerable headway has been made in the use of the latter fuel as a substitute for coke. This is particularly true in the Central States, where the supply of high-grade coke has been very limited and uncertain during the past few years and where coking coals of low sulphur content were available in quantities. In fact, with the present difference in price of coal and coke, it is possible to realize a marked saving when using a coking bituminous coal as generator fuel.

Difficulties have been encountered in the use of such fuel, but they have been overcome to a large extent. One of the chief obstacles in the use of the more general utilization of bituminous coal for water-gas manufacture is the fact that with normal operation the capacity per unit of time is reduced. This of course is a serious problem for plants operating at capacity with coke fuel. However, this difficulty can be remedied to a large extent by a changed method of operating, and can be remedied entirely by a combination of the latter with a change in the design (or proportions) of a water-gas set. The preceding statement, it will be understood, refers more particularly to a carburetted water-gas set.

PRESENT PRACTICE IN THE MANUFACTURE OF WATER GAS FROM COKE

In the manufacture of water gas from coke present practice requires that for continuous 24-hr. service the heat of combustion of all the carbon monoxide (CO) generated during the air blow be utilized in addition to the sensible heat of the gas coming from the generator.

This is doubly true when making carburetted water gas from bituminous coking coal. The reasons why

this is so are apparent when the following factors are considered.

The average value of the blue gas from coke fuel is 300 B.t.u. per cu.ft., whereas that from the coal is 335 B.t.u. Also the volume and quality of the blast gas are appreciably greater when the latter fuel is used. In other words, when making carburetted gas from bituminous coal the quality of the blue gas is so much richer than the same gas from coke that less oil is required to carburet it to a given standard. Therefore less heat is required for heating the checker chambers. This condition is aggravated by the fact that more and richer blast gas is available than ever, and must be wasted at the stack in large quantities when making gas to a standard lower than 565 B.t.u. The lower this standard the greater the quantity of blast gas wasted. Therefore, with the present tendency toward lower standards for city gas, the benefits to be realized by the utilization of a waste heat boiler are at once apparent.

The general practice in the past in the use of waste heat boilers has been to utilize only the sensible heat of the gas, no consideration being given to the heat of combustion of the excess combustible blast gas. This is perhaps due to the fact that when making carburetted gas to a 600 B.t.u. standard or better, using coke fuel, there is but little combustible gas wasted, since more oil is used per 1,000 cu.ft. of gas and the percentage of blue gas in the finished gas is lower. The changes brought about by the use of bituminous coal as generator fuel and by the lower gas standard materially alter this condition and make it particularly desirable to supply a combustion chamber in conjunction with a waste heat boiler for utilizing the heat of combustion of the waste blast gas.

ADVANTAGES OF USING BITUMINOUS COAL AS WATER-GAS GENERATOR FUEL

In drawing attention to the use of bituminous coal as generator fuel it is not my purpose to claim that it is better fuel than coke but to point out that:

1. Carburetted gas can be made from it cheaper than with coke, due to the fact that although slightly more generator fuel is used per 1,000 cu.ft. of gas produced, the difference in the prices of coal and coke is great enough to offset this difference. Also, the oil consumption per 1,000 cu.ft. is less, due to the higher heating value of the blue gas from coal fuel.

2. A still greater economy can be realized from the use of such fuel (bituminous coking coal) when a properly designed waste heat boiler with a suitable combustion chamber is provided.

The Bureau of Mines in its investigations of the use of central bituminous coals as water-gas generator fuel, conducted at its mining experiment station at Urbana, Ill., has made a special study of the design of types of water-gas sets using coal. A report on the results of the study of this problem, entitled "Water-Gas Apparatus Designed for Use With Bituminous Coal as Generator Fuel," by William W. Odell, has just been completed, and will appear as a Bureau of Mines publication. Another paper to be published by the bureau of interest to those concerned in the manufacture of carburetted water gas is a report of experiments made during July and August, 1920, in the use of mixed fuels, coal and coke, on a commercial scale, making over 1,000,000 cu.ft. of gas a day.

Density of Aluminum From 20 to 1,000 Deg. C.

Experimental Methods for Measuring With Precision the Density of Liquid Metals, and Figures for the Results When Applied to Pure Aluminum — Derived Data of Importance Are Solid Shrinkage, or Pattern Allowance, and Solidification Shrinkage

By JUNIUS DAVID EDWARDS* AND T. A. MOORMANN†

ONE of the most interesting properties of aluminum from the standpoint of usefulness is its low density, and innumerable determinations of its density have been made. This work has nearly all been confined, however, to the observation of the density at "room" temperatures. In the technology of aluminum, the density of the liquid metal is a significant factor and there are no accurate data on the density of liquid aluminum in the literature. Furthermore, there has not always been a satisfactory correlation of the density of the material with its chemical composition and physical structure. It has been necessary, therefore, in some of our work to determine certain of these constants of aluminum and its alloys. This work has not only made available an exact knowledge of the density under varying conditions but has led to some very interesting observations and conclusions regarding the process of solidification of aluminum and its alloys. These results are of particular interest in connection with the casting of aluminum alloys. This paper is one of a series which will describe the work and the conclusions reached.

The term density, as used in these articles, may be defined as the mass of the metal in grams per milliliter. The density multiplied by the factor 0.0361 gives the mass in pounds per cubic inch. These values refer to weighings *in vacuo*; weighings made in air with brass weights and an equal arm balance will be about 0.03 per cent less. The specific volume is the reciprocal of the density or the volume in milliliters per gram of mass.

EXPERIMENTAL METHODS

The density of metal at room temperature has been determined in the usual manner by determining the apparent loss in weight when immersed in water. A platinum wire 0.10 mm. in diameter was used for supporting the specimen. No correction has been made for the effect of surface tension on the wire, because in nearly every case the correction is much less than one part per thousand. All weighings are corrected to *in vacuo*.

The determination of the density of the liquid metal presented greater difficulties. An attempt was made to determine the density by determining the apparent loss in weight of a sinker immersed in the metal. Fused quartz appeared to be the material best adapted for the construction of the sinker because of its low coefficient of expansion and it was hoped that it would not be seriously attacked by the aluminum. Because the density of fused quartz is insufficient to insure its sinking in liquid aluminum, a hollow quartz sinker was constructed with a cylinder of nickel or iron inside to increase its weight. A short, slender, quartz rod 1 mm.

in diameter was attached to the top of the sinker, and this was suspended by a platinum wire. The sinker is illustrated in Fig. 1. A number of results were obtained with this design of sinker, and they are in fair agreement with the results obtained by the densimeter method to be described later. The quartz sinkers are, however, quite rapidly attacked by the metal, particularly at temperatures above 700 or 800 deg. C., and the behavior of the sinker becomes erratic and the results unreliable. This method was accordingly abandoned in favor of another method. However, such a sinker would give very satisfactory results in contact with a metal or liquid which did not attack it and they can be readily constructed with a little practice.

Densimeter of Frary and Edwards. It has been found possible to determine the density of liquid metals with good precision by means of a densimeter devised by Dr. F. C. Frary and one of the authors. Fig. 2 shows a graphite densimeter of this type which was used with liquid aluminum and its alloys. The small inner crucible is completely filled with metal at a temperature somewhat below that at which its density is to be determined, and the cover is screwed down tight by means of two steel screws. The space between the inner and outer crucibles is filled with aluminum until the surface of the metal is about 0.5 in. from the top of the inner crucible; this bath of metal aids greatly in securing a uniform and constant temperature in the inner crucible.

The temperature of the furnace is then slowly increased until the bath of metal shows the desired temperature as measured by a platinum-platinum rhodium thermocouple, and then is carefully held at this temperature for from five to ten minutes. Great care is exercised to reach this temperature slowly, and not to exceed it at any time. As the temperature rises, the aluminum in the inner crucible expands and completely fills the crucible. The excess runs out through a very small channel formed by a groove in the top face of the crucible and the tightly fitting cover. Any beads of metal adhering to these openings are detached, the crucible is removed from the furnace, the metal in the surrounding bath is poured out, and the crucible is allowed to cool. When cold, the ingot is removed and weighed. The volume of the inner crucible has previously been determined by weighing the volume of mercury just required to fill it. The volume of the crucible at the temperature of measurement is calculated by means of the expansion coefficient of Acheson graphite, as determined by Day and Sosman.¹ This correction is

small—only 0.65 per cent at 1,000 deg. C. The density is readily calculated from the weight of the metal and the volume it occupied at the temperature of the determination. This method was considerably more precise than the sinker method but required a longer time to carry out a series of determinations.

DENSITY OF SOLID ALUMINUM

The density of a metal is subject to variation from changes in both composition and structure. As a result, the data on the density of aluminum as well as the density of other metals are frequently both conflicting and confusing. When metals are cast there are certain voids left in the metal as cracks, pores, etc. The application of pressure to the metal as in rolling or cold working tends to eliminate these voids, with a resultant increase in density. It has been observed, however, by a number of investigators that continued working of many metals eventually results in a decrease of density, and that annealing of these hard-worked specimens results in an increase of density. The explanation of this interesting phenomenon as proposed by Beilby² lies in his "amorphous phase" theory. According to this theory the deformation of the metal results in the transformation of small amounts of the crystalline metal into an amorphous modification possessing properties similar to those of a super-cooled liquid. This amorphous metal should have theoretically a lower density than the crystalline modification, and so its production lowers the average density of the metal. Upon annealing, the amorphous metal crystallizes and the density increases. These changes are not large in magnitude, but are apparently well authenticated. A good review of the evidence has been given by Johnston and Adams.³ More recently Hull⁴ has shown that mechanical working tends to change the crystal structure of aluminum from a face centered cubic lattice to a hexagonal arrangement. The changes in density under discussion might possibly be accounted for by some such change in crystal structure without recourse to the amorphous phase theory. In the case of aluminum, Kahlbaum⁵ found the density of a sample of hard-drawn aluminum wire to increase from 2.6995 to 2.7031 upon annealing. Brislee⁶ in an extensive series of experiments found variations of the same magnitude between hard-drawn and annealed aluminum wire, and

somewhat smaller differences in the case of metal which had not suffered as great deformation.

A number of tests were made by the authors to confirm these observations; a summary of these tests is given in Table I.

The sample of very pure metal (99.75 per cent) taken from the pig was increased in density from 2.686 to 2.703 by rolling; annealing produced no further change, however. Two samples of hard-rolled sheet (99.23 per cent) decreased slightly in density upon annealing. A cast sample of low-grade metal decreased in density with compression, and later increased upon annealing. According to the theory, the increase of density upon annealing should be greatest in the specimens which had suffered the greatest deformation. To test this point, samples of conductor wire were twisted almost to the breaking point. In the two tests made, there was an increase in density upon annealing, and the increase was greatest in the case of the wire most severely deformed. The decrease in density caused by annealing of the hard-rolled sheet referred to may have been caused by expansion of pores and fissures during annealing with its consequent crystal growth. The last-mentioned specimens had not received severe mechanical treatment.

It may be of interest to calculate the percentage of metal which must be present in the amorphous form to account for the observed changes in density. Take, for example, the sample of No. 10 wire which increased in density from 2.703 to 2.706 upon annealing. If it is assumed that the density curve of the solid amorphous metal is continuous with that of the liquid, then by extrapolation of the graph of Fig. 3, the density of amorphous aluminum at 20 deg. C. would be approximately 2.55. A simple calculation from the corresponding specific volumes shows that the presence of 1.8

FIG. 2. DENSIMETER OF FRARY AND EDWARDS FOR LIQUID METALS

TABLE I. EFFECT OF PHYSICAL TREATMENT UPON DENSITY OF ALUMINUM

Purity of Sample, (per Cent Al)	Condition and Treatment of Sample	Density, (20 Deg. C.)
99.75	Sample sawed from pig.....	2.6827
	Sample sawed from pig.....	2.6861
	Same, cold rolled from $\frac{1}{8}$ to $\frac{1}{16}$ in.....	2.7031
	Preceding sample, annealed 15 min. at 850° F.....	2.7030
	Same, annealed 2 hr. longer.....	2.7030
99.23	Hot rolled to $\frac{1}{8}$ in.; finished to 0.22 in.; not annealed....	2.7078
	Same, after annealing.....	2.7069
	Hot rolled to $\frac{1}{8}$ in.; finished to 0.27 in.....	2.7077
	Same after annealing.....	2.7057
98.25	Small ingot cast in graphite.....	2.7279
	Same, compressed under load of 50,000 lb.....	2.7258
	Same, after annealing at 850° F.....	2.7266
99.49	Wire from aluminum cable.....	2.7064
	Another sample of same after twisting severely.....	2.7046
	Preceding sample annealed.....	2.7055
	Another sample after twisting very severely.....	2.7052
	Same, after annealing.....	2.7091
99.5	Hard drawn aluminum wire, No. 10 gage.....	2.7029
	Same, after annealing.....	2.7063
	Hard drawn aluminum wire, No. 6 gage.....	2.7019
	Same, after annealing.....	2.7048

per cent of amorphous metal of the assumed density would account for the change in density from 2.703 to 2.706.

Although we have contributed very little to the evidence on this phase of the investigation, the following conclusions seem warranted:

The working of cast aluminum increases its density by the elimination of voids. A point may be reached, however, at which further deformation of the metal results in a decrease in density, and the annealing of such metal again produces an increase in density. This

⁶Brislee, *Trans. Faraday Soc.*, vol. 9, p. 162 (1913).

latter effect is best explained by the production of amorphous metal during working, which modification has a lower density than crystalline aluminum.

Examination of the available data indicates, in the authors' opinion, that the density of pure annealed

FIG. 3. DENSITY OF ALUMINUM, 99.75 PER CENT Al (DOTTED PORTION OF GRAPH WAS CALCULATED)

aluminum (100 per cent aluminum) is very close to 2.700. Samples of hard drawn wire of high purity may have densities only slightly lower than this value (for example, 2.699 or 2.698), caused by the mechanical working. Much lower values than these indicate the presence of voids. Small increases in the amounts of the usual impurities present cause an increase in density as indicated in Table IV.

THERMAL EXPANSIVITY OF ALUMINUM

A knowledge of the thermal expansivity of aluminum can be used to calculate the density of aluminum at higher and lower temperatures than "room" temperature. A summary of the available measurements is given in Table II.

TABLE II. THERMAL EXPANSIVITY OF ALUMINUM

Observer	Thermal Expansivity $\Delta l/l_0$	Temperature Range, Deg. C.	Purity of Metal Tested
Bureau of Standards ⁷	$(22.31t + 0.01115t^2) 10^{-6}$	15 to 295	Si = 0.45% Fe = 0.35%
Dittenberger ⁸	$(22.536t + 0.017071t^2) 10^{-6}$	0 to 610	"Pure"
Jaeger and Scheel ⁹	$(22.9t + 0.009t^2) 10^{-6}$	-78 to 500	Al = 99.6%

These results show some little variation, and we are adopting for the present the value obtained by the Bureau of Standards. The Bureau of Standards is also determining the expansivity of a sample of 99.75 per cent purity, but the results are not yet available.

⁷Bureau of Standards, Circular 76 (1919).

⁸Dittenberger, *Z. Ver. deutsch. Ing.*, vol. 46, p. 1,532 (1902).

⁹Jaeger and Scheel, *Elektrotech. Zeit.*, p. 150 (1919).

The density of the metal might be determined directly at the higher temperatures by the method of hydrostatic weighing if a suitable medium could be found. Oil might be used up to 300 deg. C., but beyond that temperature we have been unable to find any mixture of fused salts which would remain sufficiently constant in density to give satisfactory results.

DENSITY OF LIQUID ALUMINUM

Using the densimeter method outlined in a previous section, the density of aluminum has been determined from the melting point to slightly above 1,000 deg. C. The expansion is apparently linear over this range. The results of these tests are given in Table III. In a later section will be found a table of densities more convenient for use, and which have been taken from the "smoothed curve" fitted to the following data. For the sake of

72	0.38	0.53	0.32	0.52	98.25	822	Densimeter.....	2.362	+ 0.08
72	0.38	0.53	0.32	0.52	98.25	912	Densimeter.....	2.335	- 0.04

NOTE.—Four determinations have been omitted from the table, as having been obtained with a defective crucible; the results of these determinations were so far off as to be obviously incorrect.

Jouniaux with a quartz crystal as the sinker. They report values about 3 per cent higher than ours on metal for which they claim a purity of 99.48 per cent. The density of this metal is given as 2.794 at 20 deg. C., so there is obviously something wrong either with their technique or their analytical results, because metal of the stated purity could not possibly have a density as high as 2.79. Richards determined the weight of aluminum filling an iron mold of known volume and estimated the density of "molten aluminum" (temperature not specified) to be 2.54, which value is also high.

TABLES AND CURVES OF DENSITY, 20 TO 1,000 DEG. C.

In Table IV are shown the values for the density of several grades of metal at various convenient temperatures. The values for the solid metal at high temperatures were calculated by means of the expansion formula referred to in the preceding section. The values of liquid density were taken from graphs plotted from the data of Table III. In Fig. 3 the density of "A" (99.75 per cent aluminum) is shown graphically.

SHRINKAGE OF ALUMINUM

From the preceding data several interesting conclusions may be drawn regarding the shrinkage of aluminum in casting. The "solid shrinkage" of the pattern maker is the linear contraction in cooling from solid metal at 658 deg. C. to room temperature. As calculated from the expansion formula this amounts to 0.22 in. per ft. Tests made on bars cast between two graphite blocks, rigidly held a known distance apart, gave the value 0.21 in. per ft., which is in quite fair agreement with the calculated value.

The foundryman is also interested in what may be called the "solidification shrinkage" and the "liquid shrinkage." The solidification shrinkage may be defined as the percentage change in the volume of the metal in cooling from a liquid at the freezing point to a solid at the melting point of the metal. In the case of a pure metal, the freezing point and the melting point are identical. It is this shrinkage which is responsible for the pipe which is formed when the metal is cast. The

be correspondingly greater. In Table V are given the values for this total shrinkage from various temperatures as calculated from the graph of Fig. 3. There is also included an actual measurement of the shrinkage in a small experimental ingot. The method used was to cast an ingot in a small graphite crucible of known volume (about 240 c.c.) and then to measure accurately the volume of the pipe by weighing the volume of contained mercury. The volume of the pipe, corrected for solid shrinkage, was then expressed as a percentage of the original volume of the metal. The pouring temperature of the ingot was 1,550 deg. F. (843 deg. C.), and it will be noted that if we make the reasonable assumption that the average temperature of the metal was about 100 deg. C. lower at the time the filling and leveling of the crucible of metal was completed, then the calculated shrinkage is in good agreement with the observed value.

SUMMARY

The density of pure, annealed aluminum (100 per cent aluminum) is estimated to be very close to 2.700. The effect upon the density of small changes in composition and changes in structure produced by mechanical working, etc., are discussed in this paper. A graphite densimeter has been developed for determining the density of liquid metals and a series of determinations carried out on liquid aluminum of various grades. The density of liquid aluminum (99.75 per cent aluminum) may be obtained from the following equation:

$$D_t = 2.382 - [0.000272(t - 658 \text{ deg.})]$$

The solidification shrinkage or volume change of aluminum on freezing is shown to be close to 6.6 per cent.

Rubber in the Manufacture of Dynamite

An interesting note on the important part played by rubber in the manufacture of nitroglycerine and dynamite will be found in *India Rubber World*, Nov. 1, 1920, p. 114.

During the nitration of the glycerine and the subsequent settling, neutralization and washing, the workmen are protected from acid burns and toxic absorptions by rubber gloves and boots. The pure nitroglycerine is conveyed to the storehouses in rubber-lined gutters.

From the storehouse the nitroglycerine is taken to the mixing house in a copper-lined, rubber-tired buggy provided with long rubber tubes for discharging the contents. The absorbents, such as sodium nitrate, ammonium nitrate or wood pulp, are added in the mixing machine, a large wooden bowl in which large hard-rubber-tired wooden wheels revolve. The loose dynamite is removed by wooden shovels to wooden tubs, thence to the packing machine, where it is packed into paraffined paper shells by means of wooden tamps tipped with rubber.

A New Sweet

The *Bulletin* of the Imperial Institute (vol. 18, pp. 123-5, 1920) reports that a sweet of remarkable potency is found in a plant called "caa-che" (*Stevia rebaudiana*), that flourishes in Paraguay. The sweet constituent is a glucoside called estevia, which is accompanied in the plant by another sweet constituent, rebaudin, probably a compound of estevia with sodium or potassium. Estevia and rebaudin are said to be respectively 150 and 180 times as sweet as cane sugar.

TABLE V. SHRINKAGE OF ALUMINUM

Temperature Deg. C.	Total of Solidification and Liquid Shrinkage From t Deg. C. to Solid at 658 Deg. C.—Percentage of Original Volume	Remarks
658	6.6	Calculated from data of Table IV.
700	7.2	Calculated from data of Table IV.
800	8.2	Calculated from data of Table IV.
	7.7	Shrinkage measured on ingot cast at 1,550 deg. F.; temp. estimated at 100 deg. C. lower at completion of filling of crucible.

liquid shrinkage is the contraction of the liquid in cooling to the freezing point and of course varies with the temperature interval through which the metal cools.

Referring to Fig. 3, the solidification shrinkage in metal changing from liquid of density 2.382 at 658.7 deg. C. to solid of density 2.55 at the same temperature is 6.6 per cent. Toepler¹² reports the solidification shrinkage of aluminum to be 5.1 per cent. In the casting of aluminum it must, of course, be poured at a higher temperature than 658 deg. and the total of the solidification shrinkage and the liquid shrinkage will

**Present Status of Industry, With Special Reference to Recent Operations in Texas—
Pyrites Versus Sulphur as a Source of SO_2 —Effect of Traces of Petroleum—
Properties and Uses—Sulphur as an Engineering Material**

BY RAYMOND F. BACON* AND HAROLD S. DAVIS†

SULPHUR plays a more basic rôle in chemical industry than any other element. Either as elementary sulphur or combined as a metallic sulphide, it is the source of all sulphuric acid. Hence any changes in the sulphur industry should be of great interest to the chemical engineering profession.

America now dominates the sulphur industry and virtually all the American sulphur is produced by three companies—viz., the Union Sulphur Co., the Freeport Sulphur Co. and the Texas Gulf Sulphur Co. These three companies produce not only virtually all the sulphur used in the United States but also a considerable surplus which is exported. The only other sulphur which normally enters the American market in quantity comes from Japan¹ and its percentage calculated on the consumption of the United States is small and is not likely to increase. Rising costs of living have meant much higher wages in Japan, as well as in other parts of the world; in fact, the percentage increase has probably been greatest in Japan, due not only to world conditions affecting all countries but to the rising standards of living of the Japanese. These facts, together with present higher transportation costs, will make it increasingly difficult for Japanese sulphur to compete on our Pacific Coast with the American product.

EXPANSION OF INDUSTRY DURING WAR

During the World War, and especially after America's entry into it, the demand for sulphur grew enormously. Some time previous to our declaration of war consideration had been given by a certain group of New York capitalists to the opening up of the sulphur deposit (known as the "Big Dome") located near Matagorda, Tex. These plans were hastened to realization by our Government's need and demand during the war for the maximum production from every possible source of sul-

phur. The plans eventuated in the formation of the Texas Gulf Sulphur Co., which, however, did not get its plants into operation until after the armistice. Production has been practically continuous since the company first mined sulphur on March 19, 1919. The plant of this company, which has been described elsewhere,² was designed to have a capacity of 1,000 tons of sulphur per day, but for months at a time during the past year it has produced on an average 2,000 tons per day. The total production for the year 1920 exceeds 800,000 long tons, while in all probability the production for 1921 will be the largest of any sulphur company in the world. The possible daily production with the present plant, under favorable conditions, could be forced to three or four thousand tons per day. The deposit contains upward of ten million tons of sulphur; and a brief description of its character is as follows:

DESCRIPTION OF BIG DOME AT MATAGORDA

The main deposit has a diameter of about 4,000 ft. and is situated 800 to 1,000 ft. below the surface of the ground. The sulphur occurs in an almost flat stratum, whose general shape is like that of a flat-topped umbrella. Above the sulphur stratum is an unconsolidated sediment consisting of bands of shale, gumbo and boulders. Below is a layer of salt and gypsum, and then a layer of salt of undetermined but very considerable thickness. The sulphur content of the deposit runs quite uniform with a slightly higher percentage of sulphur on one side of the dome. The mining operations are carefully checked, and a large-sized model of the deposit enables the engineers constantly to visualize what is taking place underground.

PRODUCTION AND STOCKS EXCEED POST-WAR NORMAL DEMAND

At the time the Texas Gulf Sulphur Co. entered the market the situation was about as follows: The Union Sulphur Co. had on top of the ground, in unsold

†Industrial Fellow of the Mellon Institute of Industrial Research of the University of Pittsburgh.

²However, no Japanese sulphur is being imported into this country at the present time.

²CHEM. & MET. ENG., vol. 20, No. 4, pp. 186-188. *Eng. Min. J.*, vol. 107 (1919), pp. 555-7.

stock of sulphur, upward of one million tons and the Freeport Sulphur Co. had several hundred thousand tons. The normal consumption of sulphur in the United States had been between four and five hundred thousand tons per annum, which quantity could be readily supplied by the two older companies.³ A new sulphur company entering the market with a large production of sulphur was therefore compelled to pursue one of two policies—either to attempt to obtain a share of the business by cutting prices or to place the sulphur in markets which had not hitherto used sulphur; in other words, to increase the sulphur consumption of the country.

With reference to the first possibility, competition based on cut-throat slashing of prices always has proved disastrous to the whole industry. Moreover,

Sulphur Products Chart

Showing Primary Industry Entered, Intermediate and Final Products as Well as Final Use.

(Prepared by Mary D. Davis)

the mining of sulphur by the Frasch process, to be carried out economically, must be conducted on a very large scale, so that even if a company under the conditions outlined above had obtained a third of a possible 500,000-ton consumption, this would not have insured profitable operation. The company has chosen what is surely the wiser course, in attempting to place its sulphur by increasing the total consumption in the industries.

It was possible to do this owing to the prevailing economic conditions. The United States had in recent years consumed annually, for the manufacture of sulphuric acid, upward of 500,000 tons of sulphur in the form of pyrites, most of which came from Spain. The older sulphur companies, either because of some agreement with the pyrites importers or because of a desire to hold the price of sulphur at a certain level, had not attempted seriously in past years to substitute sulphur for pyrites as the raw material of sulphuric acid manufacture. Importation of Spanish pyrites, due to war transportation conditions, fell off very seriously during the war years. This caused many producers of sul-

³It may be stated, in passing, that any economic data given regarding either the Union Sulphur Co. or the Freeport Sulphur Co. are subject to the usual statement on advertisements of bond sales, that is, "they are gathered from sources we believe to be reliable, but are not guaranteed by us."

PYRITES VERSUS SULPHUR AS A SOURCE OF SO₂

It is interesting, in this connection, to give just a little history, for if the subject is examined it is found that in the early days of sulphuric acid manufacture all the sulphuric acid of Europe, excepting Nord-

hausen acid, was made from brimstone. This includes the period from about 1750 to 1839, when pyrites first was used commercially for the manufacture of sulphuric acid in England. This use of pyrites was due to the fact that the Neapolitan Government in 1838 granted a monopoly for the exportation of sulphur to Taix & Co., of Marseilles, which firm immediately raised the price of sulphur from \$25 to \$70 per ton. By so doing, it killed the goose that laid the golden egg, for pyrites was substituted immediately for sulphur in most European countries and the era of high-priced sulphur was but short lived. The loss of this market

was a permanent setback to Sicilian sulphur.

The subsequent history of the sulphur industry is one of violent ups and downs. If one considers this history up until some time after Frasch made America a factor in the business, it will be noted that it has been characterized at all times by short periods of prosperity, followed by a short-sighted, selfish, destructive competition on the part of certain interests. Following this would come a period of such marked depression as to threaten the life of the entire industry, and it would be necessary for some governmental or other outside agency to exercise pressure to get the producers together on a common-sense basis and thus gradually

put the industry again on its feet.⁴ Since the time when Frasch made possible America's sulphur industry the stability of the whole industry has been much greater. While at the present time there is an extremely lively competition among the companies for business, there is every reason to believe that American common sense, spirit of fair play, and co-operation will prevent this competition going to the extent of threatening the industry itself, as has happened many times in the past. Present indications are that all the sulphur companies are pursuing an enlightened policy, in that all are doing more or less research and development work having as its ultimate object the opening up of broader markets for sulphur, of which sulphuric acid manufacture affords but one.

ADVANTAGES OF SULPHUR OVER PYRITES

For sulphuric acid manufacture sulphur has many very marked advantages over pyrites. Using pyrites means handling into the works a comparatively large quantity of material, its slow combustion in expensive roasters, a certain inevitable dust nuisance and the disposal of a large tonnage of cinder. As against this, sulphur of less than one-half the weight of pyrites for a given tonnage of acid produced is handled into the works, is burned cleanly in inexpensive equipment and leaves no residues to be taken care of. Sulphur is constant in composition, and its freedom from arsenic and other impurities allows the production of a purer acid. It is also claimed that, in practice, the burning of sulphur means a higher rate of production for a given size of lead chamber space.

These acknowledged advantages of the use of sulphur over pyrites for sulphuric-acid manufacture have been demonstrated by the willingness of acid producers to pay a higher price per unit for elementary sulphur than for combined sulphur in the form of pyrites. An example of this is the fact that one of our largest and best organized chemical companies, in making a large contract, chose sulphur over pyrites for sulphuric-acid manufacture, where the differential in offered prices was 8c. per unit of sulphur.

When one considers the present high prices of labor, the uncertainty of the copper market and the fact that sulphur may be purchased in a competing market, from concerns which have large stocks on hand, so that delivery is certain, it would seem to be a wise business policy to use sulphur rather than pyrites for sulphuric-acid manufacture even with a very large differential in price. This is especially true when one considers the other side of the situation—namely, that in buying imported pyrites the consumer is putting himself at the mercy of one large set of interests which, while it may at the present time offer pyrites at low prices and even below actual cost, will almost certainly at some time in the future reap its profit by much higher prices. It is said that imported pyrites has been offered for large contracts in this country at about 10c. per unit of sulphur, ex-vessel, Atlantic seaboard, while at the same time pyrites was selling in England, much nearer the base of supplies, at 20c. to 22c. per unit of sulphur. It reminds one somewhat of the tactics of Standard Oil in the old days before "trust-busting" became fashionable with politicians; and everyone knows that those who bought cheaply when the company was extinguish-

ing a competitor never reaped any permanent advantage, but later more than paid for temporary reductions in price.

Sulphur is today one of the few substances which have not risen in price since pre-war days. In fact, sulphur is cheaper today than at any other time in the history of the industry. The price for large contracts is about \$20 per ton, Atlantic seaboard. This makes sulphur one of the cheapest raw materials available and should, it would seem, greatly extend its usefulness. Sulphur as mined and sold by all three companies is of remarkably high grade. In fact, many so-called C.P. chemicals do not possess the purity of crude sulphur, as sold by these companies. The sulphur is free from arsenic, selenium and tellurium, and often for days at a time wells will yield a product running higher than 99.9 per cent sulphur, as calculated on a moisture-free basis; in fact, sulphur companies selling the crude sulphur on contracts guarantee the purity to be over 99 or 99½ per cent.

EFFECT OF TRACES OF PETROLEUM ON COMBUSTION

One impurity occurring in traces in the sulphur of all three companies is oil. There is a dearth of information in the technical literature respecting the subject of oil in sulphur. Since the effect of this impurity is very interesting, it is appropriate to discuss it here. The peculiar effect of oil is its influence on the burning qualities and also on the color and odor of sulphur. *A priori*, one would not assume that mere traces of a combustible substance like petroleum oil could affect adversely the combustion of another combustible substance like sulphur, but such is indeed the case.

If one will make a simple experiment by attempting to burn two small lots of sulphur, one being chemically pure and the other containing 0.2 per cent of petroleum oil, he will note the following phenomena: The pure sulphur will burn quietly until it is totally consumed; the sulphur containing the oil will burn for a very short time, when it will be observed that a thin, elastic film is being formed over its surface. Very soon combustion is taking place only in spots, and within an exceedingly short time the flame goes out, although only a small percentage of the sulphur has been consumed. The explanation is quite simple. Sulphur and oil at a moderate temperature react together to form asphalt, and if the reaction is carried to completion the final result is carbon.

In the burning of sulphur containing oil the oil reacts with the sulphur to form an asphaltic material, which quickly spreads as a film over the surface. The result, as combustion proceeds, is a film of carbon over the surface of the sulphur. The ignition temperature of carbon, or of the intermediate asphaltic material, is so much higher than that of sulphur itself or than the temperature developed during the burning of the sulphur that this film is not ignited and consequently the whole flame is extinguished.

The remedy for burning such sulphur is also quite obvious. If the devices for sulphur combustion are such as to agitate the surface of the burning sulphur or in any other way break this film of asphaltic material, no difficulty will be experienced. Acid manufacturers who use mostly modern types of sulphur burners, such as the rotary or cascade type, which allow the sulphur to drop from one level to another, have absolutely no difficulty in burning sulphur containing 0.2 per cent of oil, which figure represents more oil than any of the

⁴In this connection, see Frasch, Perkin Medal Address, MET. & CHEM. ENG., vol. 10, No. 2, pp. 73-82, and J. Ind. Eng. Chem., vol. 4 (1912), p. 139.

commercial sulphurs contain at the present time. On the other hand, many of the small paper-pulp manufacturers still adhere to types of burners in which the burning sulphur is more or less quiescent. With such a type there is no agitation of the burning liquid surface, so that some of these paper-pulp manufacturers have had difficulty in burning sulphur when they happened to obtain a shipment comparatively high in oil.

The sulphur deposits of all three operating companies are located in close proximity to oil fields. When a sulphur deposit is first opened some of the product may be high in oil, running as much as 0.2 per cent, but as production proceeds the oil becomes progressively lower until finally, for days at a time, it may amount to only 0.04 per cent, which is totally negligible, even for burners which provide no agitation of the surface. We have assumed that hot water carried this small quantity of oil from small crevices in the oil-sand formation to the sulphur below when the well was first opened. After a region has become heated up by the hot water, these traces of oil are pretty well washed out; consequently, sulphur mined later in the same area is virtually free from it. Examination of drill cores of native sulphur showed such *in situ* sulphur to be oil-free. We are informed by ex-employees of the Union Sulphur Co. that this corresponds with the experiences of that organization in heating up any new area of sulphur ground. The examination of a very large number of samples of sulphur, representing the production of all three companies, has shown quite positively that none of their sulphur contains enough oil to cause any difficulty in its combustion with rotary burners or other burners which agitate the surface of the burning sulphur during combustion. It is only very exceptionally that one will find a car of sulphur whose oil content is high enough to make difficulties in its combustion in a stationary type of burner.

PROPERTIES AND USES OF SULPHUR

Sulphur is now and is likely to be for some time one of our cheapest raw materials, and accordingly should and undoubtedly will find a much wider range of usefulness. It is by studying the physical and chemical properties of a substance that one first obtains ideas as to possible new uses therefor. The chief physical properties of sulphur are tabulated in Table I. The present tonnage uses of sulphur are presented in the chart. Those properties which suggest certain possible tonnage uses for sulphur are its very poor conductivity of heat and electricity, its resistance to being wetted by water and its inertness toward most acids, all of this combined with a fair degree of physical strength. These properties suggest heat-insulating materials, electrical insulators of various types, water- and acid-proof cements, and acid-proof construction materials.

As against the properties of sulphur which might make it very desirable for certain construction purposes are certain objectionable ones, such as its brittleness and its flammability. The brittleness can be overcome sufficiently for many purposes by making mixtures of sulphur with other materials, such as sand, asbestos, or paper pulp, or by reinforcing with wire screen. In many cases the flammability is not a serious objection.

A survey of the literature, especially the patents, on the subject of sulphur mixtures reveals that almost every conceivable thing has been suggested as a perfective admixture for sulphur to obtain a material which has all the air- and acid-resistant properties one could

desire or to get a completely resistant kind of concrete useful in building. We have tested out most of the recipes which appeared to be promising and find as usual that the claims have been much overstated. However, the ordinary mixture of sand and sulphur which has been repeatedly mentioned in the literature has merits which should make it better known. The mixture which has seemed to us the best for most uses is that of 40 of sulphur and 60 of sand (parts by weight). The tensile strengths of sulphur-sand mixtures as measured in the usual manner for testing cement were as follows:

TENSILE STRENGTHS OF SULPHUR-SAND MIXTURES

Percentage of Sulphur by Weight	Tensile Strength, Lb. per Sq.In.
25	90
35	310
40	400
45	310
50	110
100	250

We have also used other fillers which have given tensile strengths of 800 and even 1,100 lb. measured in the same manner and have to a large extent overcome the brittleness of the sulphur in some of these mixtures. Sulphur-sand briquets kept on hand for one year show no deterioration in strength. It is evident that the 40-60 sulphur-sand mixture can be used as an acid-resistant concrete, for making acid-resisting pipe, tanks, gutters, launders, etc. The manipulation of such a mixture is much like that of pouring concrete and is as follows:

Practical Manipulation. It is evident that the sand should contain no constituent which will be attacked by any material which is to come in contact with the finished product; for instance, in the case of acid tanks it should be free from limestone or other acid-soluble constituents. If necessary, it should be washed and dried. The sulphur may be melted in a kettle with constant stirring, and the sand, which has been heated separately, poured into it while the stirring is continued. Unless the sand is heated, it will lump when poured into the sulphur. When the material is thick enough (40 per cent sulphur and 60 per cent sand) it is ladled into the molds.

Considerable flexibility is possible in handling this material. For instance, a small tank was made which was 2 ft. square, 18 in. deep, and 2 in. thick. The mixture was poured into a wooden mold in twelve different lots. Although several of these lots had solidified before the next was poured upon them, nevertheless the resulting joints were strong. Apparently the hot mixture melts sufficient of the solidified part to form a solid joint. There was no contraction of the tank as a whole and no tendency to split in the mold. This mixture can be worked with a trowel, like mortar. It can also be reinforced by wire netting placed in the mold before it is poured. The specific gravity of a sulphur-sand mixture (40:60) was found to be 2.46.

Weight of 1 cu.ft.....	154 lb.
Weight of sulphur required per cu.ft.....	62 lb.
Weight of sulphur required per cu.yd.....	1,670 lb.

Taking the value of sand as \$1 per cu.yd. and of sulphur as \$20 per ton, the price of the materials per cu.yd. will be about \$18. It may be possible to decrease appreciably the amount of sulphur necessary and hence

FORMS OF SULPHUR

- Crystalline**
a. *Rhombohedral*. Stable below 96° C. (205° F.).
b. *Monoclinic*. Stable above 96° C. (205° F.).
c. *Malle of Sulphur*. Formed, e. g., by action of diluted acids on polysulphides. Generally called amorphous, but shown by Smith and Brownlee to be crystalline.
There are several other modifications of crystalline sulphur of scientific interest but not of general importance.
- Liquid**. At 113° C. (235° F.). Contains Sulphur (liquid, soluble), S₈ Sulphur (liquid, insoluble or amorphous), S₂. The proportion of S₂ to S₈ increases with the temperature.
- Amorphous**. S₂ (solid). Formed by heating sulphur above 400° C. or 752° F. and pouring in a thin stream into liquid air. Its elastic properties are soon lost.
- Black Sulphur**. "When sulphur mixed with very little oil is thrown into a hot platinum dish, a black substance is obtained which has been looked on as a modification of sulphur. The product contains 55% of sulphur and 33% carbonaceous material."—Watts, *Dictionary of Chemistry*.

Elastic Sulphur. Formed by heating sulphur above 400° C. or 752° F. and pouring in a thin stream into liquid air. Its elastic properties are soon lost.

Black Sulphur. "When sulphur mixed with very little oil is thrown into a hot platinum dish, a black substance is obtained which has been looked on as a modification of sulphur. The product contains 55% of sulphur and 33% carbonaceous material."—Watts, *Dictionary of Chemistry*.

the cost by imbedding larger pieces of crushed rock or some such substance in the mass. Tests of the material in sea water are being made, but it is too early to give results. It is apparently standing up well to date.

Pipes cast of this sulphur-sand mixture show no deterioration after one year in 5 per cent hydrochloric or 5 per cent sulphuric acid. The ordinary organic acids have no effect on such a mixture. The following extract is pertinent in this connection:

THE USE OF SULPHUR AND SAND IN SEWER PIPE JOINTS^a

In constructing a main line 36-in. sewer for the conveyance of acid waste for a pulp mill in Quebec the question arose as to what material should be used in pouring the joints. Cement was out of the question on account of the deteriorating effect acid would have upon it. A number of mills were corresponded with upon the subject, but no very satisfactory method was recommended.

Ultimately the use of sulphur and sand was suggested by the engineering department. Lead wool was considered but rejected upon the ground that the cost was high. On the other hand, sand was available on the ground from excavations and sulphur could be purchased at the dockside in Three Rivers.

The method used was as follows:

An ordinary iron boiling cauldron over an open wood fire was used for heating the sulphur and sand. The proportions were one to one. The whole was heated until the sulphur melted and a semi-liquid mass formed. Three pipes were placed vertically in the trench and by means of a galvanized conductor pipe bent at one end to fit into the flange of the pipe the mixture was poured from a ladle on the top of the trench directly into the joint. The joints of each section of the three pipes in the trench were then poured in the ordinary manner with the use of a runner.

The insides of the joints were pointed with wet clay. The joints cast and became solidified in about one hour after pouring. The length of time for solidification of course depended upon the coldness of the weather.

The joints so far have been all that could be desired, having neither blowholes nor cracks. The solidified sulphur and sand is extremely hard and the only impression made on it with a large knife was to scrape fine particles away. In appearance it is almost metallic.

One possible tonnage use for sulphur which has been arousing a great deal of interest in the last two years is its application as a fertilizer. There are two methods of application which have received attention from experiment stations. During the war, when sulphuric acid was needed for munition manufacture, Lipman, of the New Jersey Experiment Station, showed that if sulphur is composted with ground raw phosphate rock the phosphate is rendered available within a reasonably short time. Bacteria in the soil oxidize the sulphur to sulphuric acid, which acts on the raw phosphate to give available plant food. It is thus possible to make available as high a percentage of phosphoric acid as is found in commercial acid phosphate. The work has been confirmed by other experiment stations and would undoubtedly have been of great importance if the shortage of sulphuric acid had continued. Lipman has since improved the procedure by isolating and growing pure cultures of the most active sulphur oxidizing bacteria and has prepared sulphur inoculated with these. Such a product is put on the market under the name "Bac-Sul" and it is understood that the Union Sulphur Co. is interested in its sale. Although we believe that a product of this kind will do all that is claimed for it, it is doubtful whether it means any immediate tonnage outlet for sulphur. Competent agricultural authorities advise that it is nearly impossible to get the American farmer to do composting and at best the introduction

of any new type of fertilizer is a slow and tedious process. The other use of sulphur as a fertilizer consists in its direct application to the soil. The Oregon Agricultural College Experiment Station has shown very conclusively that certain soils in southern Oregon are immensely benefited in this way, so that the alfalfa crops have been greatly increased. Several of the other state experiment stations have reported the same experience for certain types of soils. In fact, results obtained by the use of sulphur as a fertilizer have in some cases been so remarkable as seriously to raise the question whether some of the standard theories on fertilizers will not have to be revised. Nearly all the experimental work through which phosphate has been given its high place as a fertilizer has been done with an acid phosphate containing considerable quantities of sulphates. Similarly, in experiments with potassium and ammonium fertilizers, the sulphates have often been used. Any change in growth or yield has been ascribed to the phosphates, the potassium or the nitrogen. The question now arises as to how much of this change in plant growth was due to the sulphur entirely apart from the other fertilizing constituents.

Correspondence with virtually all the experiment stations in the United States on the subject of sulphur as a fertilizer has elicited opinions which virtually all boil down to the following: Very many of our soils either contain enough sulphur for plant requirements or receive sufficient in the rainfall and other water. There are also very many soils on which sulphur would undoubtedly prove to be an advantageous fertilizer either because of a deficiency in sulphur or because sulphur during its oxidation would make available from the soil other needed plant foods. Work is either under way or in project in almost every experiment station in the country to obtain more knowledge on this subject, especially to find out what soils in each particular state have need of sulphur. It is probable that in time this may mean a tonnage market for sulphur, but when it is considered that there is today definite proof that the farmers of the country as a whole could use to their own profit at least ten times as much fertilizer as they do it will be realized that the building up of a tonnage use of any new fertilizer promises nothing large in the near future.

The greatest problem of the American sulphur industry at the present time is to obtain immediately available new tonnage outlets for sulphur. The solution of this problem would mean a continued prosperity to the sulphur industry and a continuance of low-priced sulphur for the greater chemical industry.

Pittsburgh, Pa.

Value of Magnesium Salts as Fertilizers

Magnesium plays an important rôle in the process of plant assimilation and it has been shown that the chlorophyll is an organic magnesium compound with a content of about 30 per cent magnesium. In a paper recently read before the German Chemical Society Dr. A. Jacob described the experimental work done during 1917-19 by the agricultural department of the Kalisyn-dicat on the influence of various magnesia-containing fertilizers on harvest yields and showed that potassium-magnesium sulphate and potassium chloride-kieserite ($\text{MgSO}_4 \cdot \text{H}_2\text{O}$) constitute efficient fertilizers for sandy and brackish soils.—*Chemical Trade Journal and Chemical Engineer*, Dec. 25, 1920.

Physical Properties of Nickel

Compilation of Literature References and Original and Unpublished Work on the Various Physical, Mechanical, Thermal, Electrical and Optical Properties of Pure Nickel

By PAUL D. MERICA

Superintendent of Research, International Nickel Co.

THE density and specific gravity of nickel vary greatly according to its chemical composition, physical condition and the mechanical treatment which it has received. Metal which has been reduced by carbon, or carbon monoxide, to a powder or sponge contains numerous voids and may have a density as low as from 7.7 to 8.0, values which have been obtained for powder and rondelles, or grain nickel.

Dense nickel, such as electro- or malleable nickel, will vary in density from 8.70 to 8.90, averaging about 8.84, which may be taken as quite closely representing the bulk of commercial material. This corresponds to 552 lb. per cu.ft., or 0.319 lb. per cu.in. (8.84 g. per cu.cm.).

CHANGE OF STATE

The melting point of nickel is given by the Bureau of Standards¹ as 1,452 deg. C. The element undergoes a magnetic transformation, accompanied possibly by a phase change at from 340 to 360 deg. C.^{2,3} The transformation point in commercial nickel, containing impurities, is lower, usually in the neighborhood of 320 deg. C.^{3,4} The boiling point of nickel has never been determined.

The heat of transformation is 1.33 cal. per gram according to Wüst,⁵ and the heat of fusion 56.1 cal. per gram.

SPECIFIC HEAT

Wüst⁵ has recently determined the specific heat of nickel (analysis not given) from 0 to 1,520 deg. C. in cal. per gram per deg. C.; his results are given in Table I.

TABLE I. SPECIFIC HEAT OF NICKEL

Temperature	Mean Specific Heat $\frac{q_t - q_0}{t}$	True Specific Heat $\frac{dq}{dt}$
0		0.1095
100	0.1147	.1200
200	.1200	.1305
300	.1252	.1409
320	.1263	.1430
330	.1306	.1294
400	.1304	.1294
500	.1302	.1294
600	.1301	.1294
700	.1300	.1295
800	.1299	.1295
900	.1299	.1295
1000	.1298	.1295
1100	.1298	.1296
1200	.1298	.1296
1300	.1298	.1296
1400	.1298	.1296
1451 (solid)	.1298	.1296
1451 (liquid)	.1684	.1338
1500	.1673	.1338
1520	.1668	.1338

Jaeger and Dieselhorst⁶ determined the true specific heat at 18 and at 100 deg. C. of a sample of nickel

containing Co 1.36, Fe 0.44, Mn 1.04, Cu 0.15, Si 0.06. They find the following values:

At 18 deg. C. = 0.1065 cal. per gram per deg. C.

At 100 deg. C. = 0.1160 cal. per gram per deg. C.

Schimpff⁷ finds the following values of the mean specific heat of nickel containing 1.5 per cent Co, 0.6 per cent Fe and 97.9 per cent Ni:

At 17 to 100 deg. C., 0.1084 cal. per gram per deg. C.

At 17 to —79 deg. C., 0.0973 cal. per gram per deg. C.

At 17 to —190 deg. C., 0.0830 cal. per gram per deg. C.

THERMAL EXPANSIVITY

Guillaume⁸ finds the thermal expansivity between 0 and 40 deg. C. of five bars of commercial nickel to be represented by the equation:

$$\frac{\Delta l}{l_0 t} = (a + bt) 10^{-6}$$

in which the values of the coefficients a and b had the following values:

	a	b
1	12.66	0.0055
2	12.52	0.0066
3	12.49	0.0070
4	12.49	0.0079
5	12.55	0.0054

Tutton⁹ finds the following values of a and b for same equation, holding between 0 and 120 deg. C.:

$$a = 12.48, b = 0.0074$$

Between 0 and 300 deg. C. Harrison¹⁰ finds that the expansivity of "pure nickel" can be represented by the following equation:

$$\frac{\Delta l}{l_0 t} = (12.80 + 0.0075t + 0.000035t^2) 10^{-6}$$

Between 300 and 1,000 deg. C. Holborn and Day¹¹ give the following equation for the expansivity, as calculated from their measurement on a nickel of which no analysis is given:

$$\frac{\Delta l}{l_0 t} = (13.46 + 0.0033t) 10^{-6}$$

THERMAL CONDUCTIVITY

The best determinations of the thermal conductivity of nickel are those of Lees¹² on electrolytic nickel, and of Jaeger and Dieselhorst⁶ on nickel of composition 1.36 Co, 0.44 Fe, 1.04 Mn, 0.15 Cu, 0.06 Si. The values obtained by them are:

Lees:

$$K_0 = 0.140 \text{ calories per second per cm. per deg. C.}$$

$$K_{18} = 0.140 \text{ calories per second per cm. per deg. C.}$$

Jaeger and Dieselhorst:

$$K_{18} = 0.142 \text{ calories per second per cm. per deg. C.}$$

$$K_{100} = 0.138 \text{ calories per second per cm. per deg. C.}$$

Fig. 1, curve 1, gives the results of determinations of Lees¹² on 99 per cent nickel bar and curve 2 by Angell¹³

FIG. 1. THERMAL CONDUCTIVITY OF NICKEL

on a nickel rod from Boker (no analysis) of the thermal conductivity at higher and lower temperatures.

ELECTRICAL RESISTIVITY

A number of precise determinations of the electric resistivity of nickel have been made, but the nickel used was in many cases quite impure and the values of the resistivity so obtained are much higher than the value for pure nickel. Table II gives several of the values which have been observed.

The most probable value for the resistivity of pure nickel from these determinations is the lowest, that of Copaux; with this lowest value is associated also the highest temperature coefficient (also the most probable). Other values are higher due to the presence of impuri-

These are as follows: Curve 1 is by Lees,¹² on a 99 per cent Ni bar. Curve 2 is by Angell¹³ on a nickel rod from Boker (no analysis). Curve 3 is by Niccolai¹⁴ on Kahlbaum nickel (no analysis). Curve 4 is by Harrison¹⁵ on a "nickel wire." Fig. 3 gives the results of one series of determinations of the influence of temperature on the temperature coefficient of resistivity by Somerville.¹⁷ At the transformation point the resistivity-temperature curve changes its slope and there is a marked change in the value of the temperature coefficient.

The Driver-Harris Co. reports its 99 per cent nickel (Grade A) wire as having a resistivity of 64.3 ohms per mil-foot (10.68 microhm per cu.cm.) at 24 deg. C., with a temperature coefficient at 24 deg. C. of 0.0041. Other grades of malleable nickel of higher manganese content have higher values of resistivity and temperature coefficient; thus, Grade D nickel, containing 4.5 per

FIG. 3. TEMPERATURE COEFFICIENT OF ELECTRICAL RESISTANCE ACCORDING TO SOMMERVILLE¹⁷

cent Mn, has a resistivity of 20.0 microhm per cu.cm., with a temperature coefficient of 0.0020.

THERMO-ELECTROMOTIVE FORCE

The curves of Fig. 8 give the results of determinations of the thermo-electromotive force of nickel to platinum, lead, copper and silver. These are as follows:

Nickel against silver is, according to determinations of Hevesy and Wolff¹⁸ on nickel wire, no analysis given, furnished by the Vereinigte deutsche Nickel Werke. Ni: Pt is calculated from the preceding results on the Ni: Ag couple, together with those of Holborn and Day on the Ag: Pt couple. Ni: Cu is according to determinations of Pecheux²⁰ on nickel wire of the following composition: Cu 0.20, Fe trace, Co 0.15, C and Si none; total impurities 0.35. Ni to Pb is according to determinations of Dewar and Fleming²¹ on Mond nickel. The electromotive force developed is such that the current flows at the 0 deg. C. junction from the Ag, the Cu or the Pt to the Ni, when the emf. is positive.

MAGNETIC PROPERTIES

Nickel is ferromagnetic at ordinary temperatures and up to the temperature of its magnetic transformation,

FIG. 2. ELECTRICAL RESISTIVITY OF NICKEL

ties which depress also the value of the temperature coefficient.

Fig. 2 gives the results of several determinations of the electrical resistivity at higher and lower temperatures.

TABLE II. ELECTRICAL RESISTIVITY OF NICKEL

Reference	Material	Electrical Resistivity Microhms per c.c.	Temperature Coefficient	Curve No in Fig. 2
Fleming ¹⁴	Electrolytic, no analysis given. Annealed in hydrogen and drawn into wire.....	6.926 at 0° C.	0.0061 (0-100° C.)	5

Jaeger and Dieselhorst ⁶	1.36 Co, 0.44 Fe, 1.04 Mn, 0.15 Cu, 0.06 Si.....	11.76 at 18° C.	0.0044 (1-100° C.)	..

340 to 360 deg. C. Above this temperature it is paramagnetic and follows Curie's law.²² Fig. 5 gives the results of some magnetic tests of nickel. In this figure curve 1 shows the induction curve for malleable nickel (International Nickel Co.) containing Ni 98.82, Cu 0.18, Fe 0.46, Mn 0.27, C 0.11, Si 0.13, S 0.022, as determined by the Burrows method. Curve 2 gives the permeability curve for same material. Curve 3 represents the induction of nickel of unknown composition as determined by Perkins,²⁴ while curve 4 gives the induction of nickel of unknown composition reported by Ewing.²³

The susceptibility of nickel in any direction is markedly diminished by the application of a tensile stress and augmented by that of compressive stress in that direction.

The permeability of nickel increases with temperature up to 300 to 340 deg. C. (Ewing²³).

SOLUTION POTENTIAL

The true reversible potential of nickel in a normal aqueous nickel sulphate solution is given by Schoch²⁵ as 0.48 volt, measured against the normal calomel electrode. Schoch attributes the higher values obtained by other investigators to occluded hydrogen.

Schweitzer²⁶ gives the value 0.612 volt for the potential of nickel powder in contact with N/1 NiSO₄ and 0.596 volt for nickel powder in contact with N/1 NiCl₂, both measured against the normal calomel electrode.

Measurement has been made by N. Isgarischew²⁷ of the potential of nickel against a solution of NiCl₂ in methyl alcohol. The combination was:

At a temperature of 25 deg. C. the potential difference was 0.247 volt.

Nickel becomes markedly passive—i.e., it behaves like a noble metal—to a greater degree than do other metals of high solution potential. This state may be established by simple immersion in strong oxidizing agents like nitric acid or bichromate solutions. This condition

FIG. 4. THERMO-ELECTROMOTIVE FORCE OF NICKEL

of passivity may often be destroyed by slight changes in the chemical environment or by scratching or mechanical shock. Pure nickel as an anode is readily rendered passive in electrolytes containing salts of oxygen acids, especially at high current densities. The presence of impurities in the anodes as well as of the chlorides or fluorides in the electrolyte tend to prevent passivity.

Coincident with the establishment of passivity, there is a pronounced drop in the solution potential.

OPTICAL PROPERTIES

One of the most important commercial properties of nickel is its ability of taking and retaining a high polish and of reflecting a large percentage of light incident on such a polished surface. For example, this is one of the properties which make the metal valuable

FIG. 5. MAGNETIC PROPERTIES OF NICKEL

for electroplating. In Table III are given the best values of the reflectivity of both nickel and Monel metal; those of the Bureau of Standards are recent (1920) and were obtained on samples of typical commercial rolled materials.

TABLE III. REFLECTIVITY OF NICKEL AND MONEL METAL

Wave Length of Light, Microns	Hagen and Rubens Values on Electrically Deposited Nickel, Per Cent	Bureau of Standards Values (1920) on Commercial Rolled Nickel, Per Cent	Bureau of Standards Values (1920) on Commercial Rolled Monel, Per Cent
0.42	56.6	61.5	57.7
0.50	60.8	63.2	59.0
0.55	64.9	64.0	60.1

800	3,730	11,900
1,000	2,900	11,900
1,200	2,480	11,900
1,300	2,480	11,900

Meyer²⁸ gives the following values for the other optical constants of nickel:

Reflectivity.....	=	65.5 per cent for $\lambda = 0.589 \mu$
Absorption index (K).....	=	3.42 per cent for $\lambda = 0.589 \mu$
Refractive index (n).....	=	1.58 per cent for $\lambda = 0.589 \mu$

ELASTICITY

According to determinations of Harrison,²⁹ Grüneisen,³⁰ Schaefer,³¹ Searle³² and Guillaume,⁸ the value of Young's modulus for nickel varies from 21,000 to 23,000 kg. per sq.mm. (30,000,000 to 33,000,000 lb. per sq.in.)

Koch and Dannecker³³ and Harrison²⁹ have determined the values of the modulus of torsional elasticity and of Young's modulus, respectively, at higher temperatures; their values are given in Table IV.

Poisson's ratio for nickel is 0.33 according to Benton³⁴.

HARDNESS

In the annealed condition the scleroscope hardness of nickel of low carbon (0.10 per cent) and manganese (0.30 per cent) will vary from 9 to 12, using a universal hammer. The Brinell hardness under 3,000 kg. pressure determined on the same material varies from 80 to 100. The effect of carbon and manganese on the hardness of annealed metal will be discussed in a subsequent article under the effect of impurities on nickel. When hardened by cold working the scleroscope hardness may be raised to 40 to 45, the Brinell hardness to 250 to 350.

TENSILE PROPERTIES

Table V gives the values usually obtained for the tensile properties of nickel of low carbon and man-

TABLE V. TENSILE PROPERTIES OF NICKEL

	Tensile Strength, Lb. per Sq.In.	Yield Point, Lb. per Sq.In.	Elongation in 2 In.	Reduction in Area

Prevention of Sugar Deterioration

The phenomenon of raw sugar deterioration is described in Bulletin 175 of the Agricultural Experiment Station of the Louisiana State University, Baton Rouge. A summary of the findings is as follows:

By the use of superheated steam in centrifugals it was possible to reduce the number of micro-organisms over 90 per cent, thereby eliminating one of the most important factors in sugar and molasses deterioration. This method is simple, economical and efficient.

A survey was made of the deterioration of a large variety of Cuban raw sugars during normal storage. The results show that the number of micro-organisms together with moisture ratio (or factor of safety) is the determining factor in sugar deterioration.

It was possible to predict from the above data whether or not deterioration would take place, thereby preventing serious losses.

Mold spores contain an enzyme capable of forming gum in sucrose solutions of all concentrations up to the saturation point.

The gum formed is levan, as indicated by its physical and chemical properties, having a specific rotation of -40 deg. a melting point of 200 deg. C., and forming levulose on hydrolysis.

The Invertase method has been successfully applied in the determination of true sucrose in the presence of gum. The gum may be quantitatively determined polariscopically by combining the Clerget and Invertase methods.

Levan is formed from nascent levulose and dextrose (obtained by the inversion of sucrose). There is evidence that the former is used to a greater extent in gum formation. In the absence of sucrose and nascent reducing sugars, slight gum formation was obtained with c.p. reducing sugars. Levan is not formed directly from sucrose, but may be formed when the latter undergoes inversion.

Appreciable concentrations of acidity or alkalinity inhibit the activity of levanase, the optimum reaction being about P_H 7.0.

Estimating Impurities From Melting Point Curve

Walter P. White, of the Geophysical Laboratory, has discussed the limitations and described the experimental procedure for using the freezing curve of nearly pure substances for estimating the amount of impurity. The results are independent of the true melting point of the pure substance and even of the absolute accuracy of the thermometer or pyrometer. In checking purity by the capillary method it is customary to work until further purification produces no change. This condition, of course, may occur when by decomposition, solution of containers or absorption from air, an attempted purification causes no change in a substance already nearly pure. Such a large source of error, as well as a heavy wastage of time, is eliminated by the new method. (*J. Phys. Chem.*, vol. 24, p. 393; May, 1920).

Rise and Development of the Electrolytic Alkali and Chlorine Industry in Europe—I

An Outline of the Electrolytic Cells Employed in the Electrolytic Alkali and Chlorine Industry of the United Kingdom, Germany, Austria, France, Italy, Switzerland, Russia and Belgium

By JOHN B. C. KERSHAW

THE production, upon an industrial scale, of alkali and of free chlorine by the electrolysis of solutions of sodium or potassium chloride is now well established, for it is rather more than thirty years since the first successful installation of this kind was started by the Elektron Co., at Griesheim, near Frankfurt, in Germany. Today electrolytic alkali works exist and are being operated in all the leading manufacturing countries where the raw materials of the industry are found; and even those who control the operation of the old Le Blanc process of alkali manufacture in the United Kingdom have found themselves at last compelled by the force of circumstances and by the changing conditions of the trade and industry to adopt the newer method of decomposing salt.

It must be remembered, however, that although Germany was the first country to operate an electrolytic alkali cell successfully upon a commercial scale, the early experimental and pioneer work in connection with this new branch of chemical industry was carried out in the United Kingdom.

An Englishman (Sir Humphry Davy) in 1807 first employed an electric current to decompose a fused salt, and in this way separated and discovered the metals potassium and sodium. Another Englishman (Michael Faraday) in 1833 discovered and formulated the laws

that govern the action of an electric current in aqueous salt solutions and determined the electrochemical equivalent of various metals; and a third Englishman (Charles Watt) in 1851 applied for a patent which may be regarded as the master-patent of the electrolytic alkali and chlorine industry, since in this patent Watt described the conditions which must be observed in an electrolytic cell in which sodium or potassium chloride is being decomposed in order to obtain caustic hydrate, hypochlorite or chlorate.

Watt's patent (No. 13,755 of 1851) is of great historical interest; but at that date the dynamo had not been perfected, and as there was no practical means of obtaining large currents for electrochemical work, the electrolytic process of alkali and chlorine manufacture described by Watt remained dormant for another thirty-five years. Had Watt been able, however, to generate larger currents of electricity for his experimental work, he would have found that the production of alkali and chlorine in an electrolytic cell upon an industrial scale was not such a simple process as he had imagined, and that the choice of materials for and construction of durable anodes and diaphragms offered problems of considerable difficulty. The secondary reactions which occur in the cells between the chlorine ions liberated at the anode and the sodium or potassium

hydrate produced at the cathode also added considerably to the difficulties of manufacturing caustic alkali by this method.

Charles Watt in fact in his patent of 1851 recognized and referred to this possible cause of loss; but in spite of his warning, the inventors and exploiters of the Richardson and Holland type of cell failed to recognize or appreciate this difficulty; and it was owing to this defect that the first electrolytic alkali works built in the United Kingdom ended in a financial failure.

CLASSIFICATION OF CELLS

The cells now being operated industrially may be classified as diaphragm and non-diaphragm cells. In the former class a porous diaphragm, composed of cement, asbestos or other material unacted upon by the electrolyte (or by the ions produced by the electrolysis), is employed to separate the cell into two or more compartments; and in this way the chlorine liberated at the anode is to a large extent prevented from taking part in secondary reactions with the sodium or potassium hydrate formed at the cathode.

The "Elektron," Hargreaves-Bird, Outhenin-Chalandre, Basel, Billiter-Siemens, Nelson, Allen-Moore, Gibbs and Townsend cells are all of this type, the chief difference between them being in the construction or design of the diaphragm and in the arrangements made for withdrawing the sodium hydrate solution from the cathode compartment of the cell before it has had time to be decomposed by the electric current. The defects of all diaphragm cells are the higher voltage required per cell and the increased costs of maintenance due to the lack of durability on the part of the diaphragm.

For these reasons the other class—namely, non-diaphragm cells—have always attracted the electro-chemist, and many of these have been patented and tried. Only two types have survived industrial trial—namely, (1) the Castner-Kellner, Whiting and Solvay cells, which employ a moving mercury electrode in the cathode compartment of the cell, and thus produce an amalgam of sodium which can be removed from the cell before it is decomposed by water with formation of sodium hydrate; and (2) the "bell" type of gravity cell, which makes use of the different specific gravities of the brine and of the newly-formed sodium or potassium hydrate solution in order to effect a separation of the two. The Aussig "bell" cell and the Billiter-Leykam cell are the only two representatives of this class in actual operation; the Richardson and Holland cell, which was tried on a large scale at St. Helens in 1896-1900, having proved a failure.

The attempts to use molten lead in place of the more expensive mercury in the liquid or moving electrode cells have also failed, after trial upon an industrial scale; the wear and tear of the cell structure and the fire dangers with this type of cell having caused the suspension of operation of the Hulin cell at Les Clavaux in France, and of the Acker cell at Niagara Falls, in America. The works where the latter cell and process were operated in fact was burned down and has not been rebuilt.

Electrolytic Alkali and Chlorine Industry in the United Kingdom

The first attempt to carry out the manufacture of caustic alkali and chlorine by electrolysis upon a large scale in the United Kingdom was made at St. Helens in

1895 by a company named the Electro Chemical Co., with a capital of \$720,000. This company operated the Richardson and Holland bell type of gravity cell, and after a disastrous career of five years the works was closed down and the plant was sold in 1900 for the reasons already mentioned.

In the meantime the British Aluminum Co., of Oldbury, Birmingham, had been experimenting and developing the mercury cathode type of cell designed and patented by their chemist (H. Y. Castner) in 1892 and 1893; and in 1895-96 a company was formed and a works was planned for operation of what is now known as the Castner-Kellner process, at Weston Point, near Runcorn. This works started manufacture in 1897, and today is the largest and most successful electrolytic alkali works in the United Kingdom.

The Middlewich works, of what was originally the Electrolytic Alkali Co., was erected in 1899-1900, a very long interval having been allowed to elapse between the patenting of the Hargreaves-Bird type of diaphragm cell, in 1892-93, and its industrial development upon a large scale.

The last-named company and works have had a very checkered career, for at the end of 1910 they were forced into liquidation, and the plant, after lying idle for some time, was purchased for a comparatively small amount in 1914 by a new company (the Electro-Bleach & Byproducts Co.) and is again in operation.

In that same year the board of directors of the United Alkali Co., which controls the manufacture of alkali and bleaching powder by the Le Blanc process in the United Kingdom, decided to adopt and work an American type of electrolytic cell for the decomposition of brine and to gradually change over from the Le Blanc to the newer process. The outbreak of the war, however, delayed this change, and the large electrical generating station (the erection of which is now nearly completed) on the banks of the River Mersey, at Widnes, represents the first stage of this most interesting and striking development of the electrolytic process of alkali manufacture in the United Kingdom.

As the chairman of the company remarked at the annual meeting of the shareholders at which this change was announced, it was fortunate for the Allies that the change in the process of manufacture had not been made before the war broke out, since the large plants for sulphuric acid manufacture possessed by the United Alkali Co. were immediately placed at the disposal of the government in 1914 for the purpose of the war department, and the works at Widnes contributed a very large proportion of the concentrated sulphuric and nitric acids required for the production of high explosives during the period 1914-1918. Now that peace is once more restored, the delayed plans are being proceeded with, and it is expected that the first unit of the generating plant and of the connected installation of Gibbs cells will be in operation in the works of the United Alkali Co., at Widnes, before the end of this year.

THE CASTNER-KELLNER CELL AND PROCESS

The original Castner cell was constructed of slate, and was of comparatively small dimensions—namely, 72 in. long by 36 in. broad, and 6 in. deep. The cell is shown in sectional elevation in the diagram Fig. 2, and is seen to consist of three compartments, formed by two hanging slate partitions which dip into the

mercury lying on the floor of the cell. The solution of brine was fed into the two end compartments of the cell, which were completely closed and contained the anodes of graphite or carbon. The center compartment of the cell was open, and contained water. On passing an electric current of 1,300-1,400 amp. at 4½ volts through this cell, chlorine gas of exceptional

FIG. 2. THE CASTNER-KELLNER MERCURY CELL

purity, owing to the absence of OH anions, was liberated in the closed anode-chambers, and was conducted away; while the metallic sodium liberated at the surface of the mercury was at once absorbed by this and formed an amalgam. The cell was mounted with one end fixed and the other free, in such a manner that a slight but slow rocking movement could be given to the free end of the cell by means of an eccentric mounted upon a revolving-shaft which ran the whole length of the building in which the cells were placed; and the transfer of the sodium mercury amalgam from the anode-chambers of the cell to the central compartment, where it came into contact with water, was thus automatically effected.

The Kellner improvement of the Castner mercury cell consisted in making use of iron as the cathodic terminal of the cell in place of the mercury, a group of iron rods being so arranged in the central compartment of the cell that they were in electrical contact with the sodium mercury amalgam, and on treatment and decomposition of the amalgam by the water acted as the discharge point for the hydrogen gas. This improvement prevented the loss of mercury which had occurred due to the discharge of the hydrogen ions at its surface, and also reduced the emf. required to operate the cell, since the series $\text{Hg.Na-H}_2\text{O-Fe}_2$ pro-

duced a plus emf. The solution of sodium hydrate obtained in the central compartment of the cell was almost entirely free from chloride and could be concentrated to yield a very pure solid caustic without removal of the NaCl and other impurities by the usual "salting-out" process.

The original installation of the Castner-Kellner cells at Weston Point (Fig. 2) comprised 250 cells of the type just described, connected up in ten series of twenty-five cells each, the whole being supplied with electrical energy from 1,000-hp. steam-plant consisting of Willans and Robinson high-speed engines and Mather and Platt dynamos.

The works was quite successful from its start in 1897, and its record since that year has been one of continuous expansion of its manufacturing activity and of increasing profits for its shareholders. By 1905 the capacity of the plant had increased to 4,000 hp., and a change from steam to gas as source of electric power was inaugurated in that year by the erection of the first 800-hp. unit of a Mond gas plant, the original steam plant being scrapped as uneconomical and out of date.

The development of the manufacturing operations has proceeded even more rapidly during the last ten years. According to the latest official information, the works now (1920) has a total capacity of generating and decomposing plant of 25,000 kw. and the gas power plant, erected in 1907-1910, has been scrapped in its turn, in order to install a modern steam-turbine generating plant. In this new plant the boilers are of the Babcock & Wilcox marine type, having a steaming capacity of 34,000 lb. per hr., and generate steam at 200 lb. pressure for the turbo-generators.

THE SOLVAY CELL

The mercury cell now used at this works, however, is of another form from the earlier type, since the

FIG. 4. THE SOLVAY MERCURY CELL

original Castner-Kellner cell described above was not adapted for operating upon a very large scale. According to Allmand, the cell now used is of the Solvay type, first employed at the Solvay works at Jemeppe in Belgium and worked there up to the outbreak of war. The cell (see Fig. 4) consists of a large slightly inclined rectangular cement trough, through which the mercury is circulated by means of an Archimedean screw. The brine flows through the trough from end to end in the same direction as the mercury, and carbon anodes are employed, terminating only 10 to 15 mm. above the surface of the mercury. The layer of the latter metal maintained on the floor of the cell is a very thin one, and the rate of movement is such that an amalgam of suitable concentration is obtained. This amalgam is decomposed in a separate vessel with the

FIG. 3. CASTNER-KELLNER ALKALI WORKS. ORIGINAL CELL ROOM AT WESTON POINT

aid of water, and the regenerated mercury is then returned to the electrolytic cell.

The cells at Weston Point take 4,000 amp. and make use of carbon in place of platinum as anode material. From 8 to 10 amp. of current is stated to pass per kg. of mercury employed in the whole cell.

The chief manufactures of this works during the war were pure alkali and liquid chlorine, the chlorine gas obtained from the mercury cell being exceptionally pure and therefore specially suitable for liquefaction. The manufacture of caustic potash of a very high degree of purity is another product; and metallic sodium is also

reason a mixture of steam and carbonic acid is blown into the cathode chamber of the cell; and these chambers, containing only steam and gas in place of any liquid electrolyte, are the distinctive feature of the Hargreaves-Bird cell. The cells were made of large dimensions, 5 ft. high, 10 ft. long and 14 in. wide, and decomposed about 224 lb. of sodium chloride per twenty-four hours. The current used was 2,000 amp. at 4½ volts.

As already stated, the first patents for the Hargreaves-Bird cell were taken out in 1892-93, and the cell received a very lengthy trial at Farnworth, near Widnes, before the Electrolytic Alkali Co. was formed, and a large works was erected at Middlewich, in Cheshire, in 1899.

The original installation comprised a steam-driven electrical generating plant of 2,000 hp. and eighty cells of the type described above. The anodes were built up from gas-carbon, by the method shown in Fig. 6. The cathodes were constructed, as already stated, of copper gauze, and were pressed tightly against the outer surface of the diaphragms, thus assisting to support these against the hydrostatic pressure of the liquid in the central (anode) compartment of the cell.

The construction of large and durable porous diaphragms, which could not be made too thick lest they should increase unduly the emf. required for working each cell, was one of the chief difficulties attending the operation of the Hargreaves-Bird process; the other was that carbonate of soda was not so profitable to manufacture as caustic soda. For these and other reasons the Electrolytic Alkali Co. was not able to earn adequate profits upon its capital, and as already stated it was obliged to cease manufacture and to go into liquidation about ten years ago.

The new company, entitled Electro-Bleach & By-

FIG. 5. VERTICAL SECTION OF HARGREAVES-BIRD CELL

manufactured by the electrolysis of fused caustic soda, according to the method patented by Castner in 1890.

THE HARGREAVES-BIRD CELL AND PROCESS

The Hargreaves-Bird cell differs from the Castner-Kellner and Solvay cells in nearly every respect, for it is of the diaphragm type and contains liquid only in the closed central anode compartment or chamber. The construction of the cell may be best understood by reference to Fig. 5, which is a vertical cross-section of the cell, somewhat diagrammatic in form. The inner chamber contains the anodes, which are built up from blocks of gas-carbon; it is entirely closed, and is fed with a solution of common salt or (as at Middlewich) with natural brine from the salt-beds, after a preliminary treatment to remove impurities. It is closed on each side by a porous diaphragm, strengthened on its outer side by a screen of copper-gauze, which also functions as cathode of the cell. The two outer cathode chambers contain no liquid beyond the condensed steam and CO_2 gas, which is passed into these chambers and removes the soda as it forms upon the surface of the wire gauze cathodes. This solution trickles down the cathodes and is drawn off at the base; a solution containing from 10 to 16 per cent sodium carbonate is obtained.

It has been found more economical to produce carbonate of soda than caustic soda in this style of cell, since the union of carbonic acid gas with the sodium hydrate at the surface of the cathode produces a plus emf. and also assists in removing the sodium hydrate as it is formed from the action of the current. For this

FIG. 6. ANODE OF HARGREAVES-BIRD CELL

products, Ltd., which purchased the plant in 1914 at a very low price and remodeled a large portion of it, still operates the Hargreaves-Bird cell and process at Middlewich in all essentials as described above. The cells, however, are now constructed of iron, lined with cement, and are built of 2,500 amp. capacity. The electrical generating machinery has been increased to

a capacity of 7,000 kw., and a change has been made from the use of high-pressure steam to low-pressure steam in certain of the processes, resulting in a very large economy. To enable the steam to be employed to the best advantage non-condensing reciprocating engines, direct-coupled to the generators, have been installed; while the additional power required is made up by condensing turbines. A further change made has been to increase the pressure of steam for the turbines from 150 to 210 lb., the steam being superheated to a temperature of 450 deg. F. The boiler-plant consists of seven large Babcock & Wilcox boilers, working at a pressure of 210 lb. and carrying a superheat of 150 deg. F. The plant within the power house consists of four reciprocating horizontal non-condensing steam engines driving direct-current generators, and three turbine sets, which by means of speed-reduction gearing drive also direct-current generators. The greater part of the current is employed for electrolytic work and is generated at the comparatively low emf. of 150 volts.

During the last five years, or since its inception, this company has been operating under the war conditions of inflated prices and has been able to earn very satisfactory profits for its shareholders. Whether it will be able to do so under the post-war conditions of trade and industry remains for the future to disclose.

Its products are bleaching powder, carbonate of soda, caustic soda, hyposulphite of soda and vacuum salt.

The managing director of the company in a recent letter stated that he has from time to time compared the results obtained by other types of cell with those obtained by the Hargreaves-Bird cell, and that he is satisfied that with the improved type of cell now employed the Hargreaves-Bird cell can easily hold its position.

The controlling interest in this company and in the Castner-Kellner Co. has now been obtained by Brunner, Mond & Co., which by an exchange of shares with the holders of the ordinary share capital in the two electrolytic alkali companies has secured the amalgamation of these two undertakings with its own larger firm.

THE GIBBS CELL AND PROCESS

The Gibbs cell is of the vertical diaphragm type, and in this respect resembles the Hargreaves-Bird cell. The cell and diaphragm, however, are constructed of cylindrical form, in order to obtain greater strength in the diaphragm; and the cathode which surrounds the latter is constructed with a number of inward projections or points, which are imbedded in the diaphragm and thus reduce its electrical resistance.

Both faces of the diaphragm are submerged, and in this respect also the cell differs from the Hargreaves-Bird cell.

The construction of the cell will be understood from Fig. 7, which gives the sectional elevation and is reproduced from the English patent of 1907. The combination of diaphragm and cathode is seen in section at the points marked 8 and 9, the diaphragm being made thicker at the bottom than at the top, in order to contract the increasing rate of percolation of the brine from the anode chamber due to hydrostatic pressure. The diaphragm may be made of asbestos or any other suitable material which is permeable and is not attacked by the brine or by the products of the electrolysis. The cathode jacket may consist of a sheet of steel or other

suitable metal, held in place by clamping bands or by other means.

The projections and indentations of the cathode plate which form the novel feature of the Gibbs cell are obtained either by simply punching holes through the annular sheet and then pressing it round the diaphragm with the rough edges on the inside or the sheet may be corrugated longitudinally and pressure be used again to force the projecting ridges of metal into the material of the diaphragm. According to the patent specification, the special advantages of this form of cathode

FIG. 7. THE GIBBS CELL

result particularly "from the same having points or projections entering the diaphragm" and also from the creation of "take-off" chambers or cups, which remove the caustic soda formed in their interior from the action of the current, and thus reduce the electrical losses due to the liberation of OH anions.

A further advantage claimed for this type of diaphragm is that the same permeability can be maintained for a very considerable time, whereas according to the patentee the permeability of the ordinary diaphragm decreases gradually, owing to clogging of its pores with the impurities of the electrolyte.

The following description of the action of the points on the cathode is taken from the patent specification:

As the solution passes outwardly through the diaphragm where alkaline chlorides are treated, the caustic alkali will form upon the projections or points of the cathode. The bulk of the electrolysis takes place at these points or projections, and as the caustic alkali is formed, the flow of electrolyte carries it outwardly through the holes in the cathode and out of the region of electrolytic action. By thus carrying it away as it is formed, I avoid decomposing of the caustic alkali itself, and increase the efficiency of the cell.

In the case of the cathode having the vertical passages, the liquid will flow either up or down along these passages and obtain the same result of carrying away

FIG. 8. UNITED ALKALI CO.'S PLANT AT WIDNES, UNDER CONSTRUCTION (EARLY IN 1920)

the products as they are formed. In both cases the electric current will flow mainly to the points or projections imbedded in the diaphragm, and there will be little or no electrolytic action in the troughs or portions more remote from the anodes.

The outer body of the cell is constructed of iron or any other suitable material, and the carbon anodes are securely fastened to the annular heavy flat ring which forms the top of the cell. This top can be removed, together with its attached carbon rods, in one operation by means of an overhead traveling crane when the cell is undergoing cleaning or repairs. The annular ring to which the diaphragm and cathode are attached can also be removed in a similar manner, and the rapidity and ease with which the cell can be dismantled is considered one of its good points.

No figures for its current or energy efficiency or for the strength and purity of the chlorine and caustic soda solution produced have yet been published; but the Gibbs cell had been used for some years in America by the Pennsylvania Salt Co., at Wyandotte, Mich.; and the United Alkali Co. before adopting it for its new installation at Widnes became convinced by exhaustive tests there and elsewhere that the claims made for it can be substantiated.

PROXIMITY TO WATER SUPPLY MORE IMPORTANT THAN NEARNESS TO FUEL SUPPLY

Fig. 8 shows the power station which is now under construction at Widnes for the supply of electrical energy to the new plant. The station is situated on the banks of the River Mersey, near the L. & N. W. Ry. bridge connecting Widnes and Runcorn. The site is convenient for fuel supplies and for disposal of ashes; and, being situated on the banks of the River Mersey, a full supply of cold water is always insured. Experience has shown that an abundant supply of condensing water is even more important than proximity to coal-supply, the transport of fuel being a much cheaper proposition than the transport of condensing water or the use of cooling towers. The station has therefore the great advantage of an ample supply of condensing water.

The boiler house will be equipped with eight Babcock & Wilcox boilers, provided with up-to-date mechanical coal and ash-handling plant.

(The second part of the article, dealing with the Electrolytic Alkali and Chlorine Industry in Germany and Austria, will be published in a subsequent issue.)

Industrial Possibilities of Chia Seed Oil

A new drying vegetable oil said to rival linseed oil is claimed to have been discovered and patented by Sebastian Lomanitz, of Bryan, Tex. He states that a plant chia, belonging to the genus *Salvia* and known as *Salvia hispanica* of the *Labiatae* family, yields a seed the oil of which has all the good properties of linseed oil, even the odor. The seeds of chia are used for the preparation of a beverage which is sold publicly in the streets of Mexico. There are a number of varieties of such seeds.

The chia plant is a shrub that reaches about 5 to 6 ft. in height and the seeds are oval shaped, about 1 mm. in the longest diameter and about $\frac{1}{2}$ mm. in the shortest diameter. The yield per hectare varies between 4,000 and 1,000 kg. and in certain parts of the country two crops a year may be obtained. It is remarkable that in all classic books on vegetable oils, such as those by Lewkowitsch, Chershefsky, Beilstein and Abderhalden, there is no mention whatever that oil can be derived from this species.

Experiments performed with seven varieties of seed gave the following results: Average weight of 1,000 seeds, 1,166 g.; moisture, average, 7.33 per cent; oil average inseed, 32 per cent.

It will be noticed that the yield of oil from chia seeds exceeds the yield of oil from linseed. The test of oil obtained from seeds coming from different parts of the country gave the following data:

Sp.gr. 15.5/15.5.....	0.9341
F. F. A. (as oleic).....	1.45
Index of refraction n_D 40 deg. C.....	1.4757
Index of refraction n_D 17.5 deg. C.....	1.48354
Reichert-Meisel number	0.1
Iodine value	187.59
Hehner value	94.16
Ester value	187.49

The oil remains fluid at low temperatures, similarly to linseed oil. The residue left after the extraction of the oil was found to contain substantially 30 per cent protein and could be utilized as a valuable cattle feed.

Particular attention is called to the specific gravity of the oil, to the index of refraction, the iodine value and the Reichert-Meisel value and also the fluidity at temperatures below normal, all indicating the close relation in drying qualities between this vegetable oil and that derived from linseed. The iodine value, which is the index of the drying qualities of the oil, is substantially that of the best linseed oils.

While it is possible to derive only 29 per cent of oil from linseed, it is possible to obtain about 33 per cent of oil from seeds of chia, the method of extraction being in no way more difficult than that of linseed oil. The great yield of oil from chia seeds and the value of the residue reduce considerably the price of the finished product. In view of the fact that two crops a year may be obtained, it is natural that the oil could be manufactured at a cost considerably lower than linseed oil.

Mr. Lomanitz has introduced this seed into Texas, growing it in Houston and Bryan on a small scale with a yield of about 20 bu. an acre. He harvested the crop by hand, picking out the spikes which contain the seeds and getting out the seeds from their tiny envelopes by rubbing them against a wire screen, sifting and blowing off the chaff.

The seed is very small and it is estimated that about 5 lb. would plant an acre.

American Association for the Advancement of Science, Chicago Meeting

Notes on Papers of Interest to Chemists Which Were Presented at Chicago — Phosphorescence, Fluorescence, Activated Sludge, Single Potentials, Crystalloid Filters, Ionization and Resonance Potentials, and the Theory of Chemical Reactions

CHICAGO UNIVERSITY entertained the annual meeting of the American Association for the Advancement of Science during Christmas week with representatives from sixteen branches of science ranging from mathematics, physics and chemistry to geology, medicine and education.

GENERAL SESSIONS

Robert W. Wood gave a lecture Wednesday night on "High-Power Phosphorescence and Fluorescence," in which he defined a phosphorescent body as one which when subjected to light rays, or perhaps to ultra-violet invisible rays, itself becomes luminous and continues to emit light after the excitation has been removed. It is possible that all solids have this property, but if so most of them have periods of self-luminosity following excitation so short that they cannot be detected by present methods. A high-power apparatus has been devised which generates ultra-violet rays of singular intensity, yet invisible to the ordinary eye. They have been used for the purpose of naval signaling, in particular for finding invisible running lights for convoys. The rays are detected at the receiving point by means of a wide angle telescope with a screen which phosphoresces under the influence of the ultra-violet rays from the signaling apparatus. A similar device is of use in cancer hospitals for diagnosing pathological condition in tissues by phosphorescence.

Two lamps were exhibited which made the entire audience and auditorium phosphorescent. Faces became self-luminous with a gray tint, teeth with bright blue, while artificial teeth remained an inky black. Different dress materials phosphoresced with different colors corresponding to the properties of their various dyes, the lenses of the eyes became themselves phosphorescent, emanating rays of a light blue or lavender color.

A fluorescent body is one which receives light rays of one type and, as a result of the excitation so produced, re-emits light of a different character. There are, for example, substances which when illuminated by red light give out again rays which are green. Some varieties of red ink show this property slightly. Prof. Wood has demonstrated that fluorescence of this character is always accompanied by a chemical decomposition of some sort in the fluorescent substance. A particular example is rhodamine, which when first illuminated with blue light produces orange red. Later it gives green, and at a first stage in its chemical transformation it becomes non-fluorescent.

CHEMISTRY SECTION

Some Properties of Activated Sludge, by A. M. Buswell and C. C. Larson.—It is known from published analyses that the quantity of nitrogen in septic tank contents varies from 1 to 3 per cent, in intermittent

filter contents from 1 to 4.5 per cent, while activated sludge has from 4.5 to 6.5 per cent nitrogen content, making it useful as a fertilizer. This activated sludge is in general produced by blowing air through the sewage, causing the milkiness to disappear and the sludge to flocculate. If the material is not handled quickly, it soon decomposes again to a putrescent mass which cannot be used. It is filtered or centrifuged to remove 85 per cent of the water and then dried by heat. Acidification is beneficial to the filtering process, as it tends to cause the solids to contract. Acid also prevents the material from becoming septic and so allows slow separation by gravity. One-third of the amount of acid determined by titration with methyl orange indicator is actually necessary, for it has been found that the action depends on the intensity or H-ion concentration rather than the capacity factor.

On the Single Potentials of Arsenic and Its Position in the Electrochemical Series of Metals, by Louis Kahlenberg and Vernon Steinle.—The electrodes used were solid arsenic, arsenic plated on gold and platinum and the arsenic mirror from AsH_3 plated on a glass tube. Powdered arsenic was pressed to a bar and coated with paraffine. Finely divided metal was imbedded in gelatine or cellulose acetate. The single potentials secured were as follows:

With sawed piece of arsenic.....	—0.554 volts
and.....	—0.553 volts
With paraffine coated piece.....	—0.549 volts
With arsenic mirror.....	—0.552 volts
With pressed stick of arsenic	—0.548 volts
With powder in gelatine.....	—0.544 volts
With powder and cellulose acetate on platinum	—0.551 volts
On gold	—0.554 volts

Membranes for Separating Crystalloids From One Another, by Louis Kahlenberg.—There is no record in the literature where crystalloids in aqueous solution are separable by a membrane. The author found that a membrane prepared from thin china silk dipped in melted lanoline, the fat from sheep's wool, will separate sugar from salt or potassium iodide in aqueous solution.

An Attempt to Activate Chlorine Photometrically, by Gerald L. Wendt.—In line with the research work carried out by the author where he successfully prepared activated or ozone forms of nitrogen and hydrogen by the brush electric discharge, he has unsuccessfully attempted the same with chlorine, using mercury electrodes. The next step was to set up an apparatus consisting essentially of an ultra-violet light in a central glass tube surrounded by a second glass tube to form an annular space through which dry chlorine was passed and subsequently conducted into the dark, where it was mixed through a three-way cock with hydrogen. Tests of the mixed gases showed that no HCl was found. In other words the chlorine was not activated. The two

gases were inert compared to Draper's experiments where rapid combination is secured by exposing the mixture to light.

PHYSICS SECTION

The American Physical Society co-operated in presenting some valuable papers having a bearing on chemical topics.

The work done by such physicists as Dr. Foote and Dr. Mohler of the Bureau of Standards in determining the "Ionization and Resonance Potential" of various chemical elements and compounds is going to be very valuable to the chemist in obtaining a more intimate insight into the mechanism of activation which precedes all chemical reactions. Most chemical reactions, especially those involving carbon compounds, are not accompanied by actual ionization, so that the resonance potentials are apt to be more valuable from our standpoint. When the electron hits a molecule in such a way that its energy is absorbed, probably by the displacement of a valence electron, and the absorption is measured, the quantity is known as its resonance potential. This corresponds to a state of activation which may result in chemical action. Thus zinc ethyl has a resonance potential of 7 volts and an ionization potential of 12 volts. Carbon monoxide has a whole series of resonance potentials indicating several degrees of activation.

From the chemical standpoint this means that during the first stage it might react with chlorine or ozone. During a second stage it might react with the more active oxygen molecules and when at some of the higher stages it might react with some form of hydrogen to form formaldehyde. At all events something of the sort does take place in the leaves of plants, carbon dioxide being reduced and combined with hydrogen to form formaldehyde. This suggests a possible artificial synthesis of carbohydrates.

Another interesting thing noted by these gentlemen was that the vapors of sodium or potassium chloride at 2 mm. pressure are highly ionized, while metallic calcium vapor is not ionized. Does this mean that these salts are ionized at the same time that evaporation occurs? According to Langmuir they are already ionized in the solid crystal, and on evaporation, while there is a tendency to form pairs, there is also a tendency for some of the ions to stay apart as they do in solutions. In the calcium vapor there is nothing to remove the electrons from the metallic nucleus as there is in the salts where chlorine has a far greater attraction for the valence electron than has the metallic nucleus.

Dr. Davey, of the General Electric Co. Research Laboratory showed how X-ray crystal analysis confirmed Langmuir's postulates as to atomic structure. Langmuir has shown how the Cl^- ion and the K^+ ion have the same outer shape as the argon atom, so that all are isoteric. As each of these has eight electrons in the outer shell, they should be cubical. As a matter of fact all crystals of all the alkali halides are cubical. In a similar manner the alkaline earth oxides and sulphides are usually cubical. The iron atom having eight electrons in its outer shell is cubical. Then the Ni^{++} ion should have the same shape, making NiO a real cube, as it is. The Tl^+ ion and Pb^{++} ion lack six electrons of completing the stable arrangement corresponding to the inert gas, niton, so that they should have a cubical shape with rounded corners. This results in the formation of cubical crystals of TlCl and PbS .

A. J. Dempster of Chicago University, using the

apparatus described in *Physical Review*, April, 1918, has shown that magnesium consists of isotopes of atomic weight 24, 25 and 26 as referred to nitrogen of molecular weight of 28.

An entirely new method for the determination of isotopes has been developed by F. W. Loomis of New York University. By observing the infra-red absorption spectra of various gases with a high degree of dispersion he has shown that bands due to hydrogen chloride contain two peaks corresponding to chlorine of atomic weights 35 and 37. Fluorine and bromine do not show any isotopy by this method.

Dr. Farrington Daniels of the University of Wisconsin gave a very able summary of the present status of the radiation hypothesis of chemical reactions which is receiving attention in this country from men like Langmuir and Tolman [*J. Am. Soc.*, vol. 42, pp. 2190, 2506 (1920)]: The first part of his discussion was presented at the Chicago meeting of the American Chemical Society [*CHEM. & MET.*, vol. 23, p. 563 (1920)]. Daniels has shown that the decomposition of nitrogen pentoxide is monomolecular in gaseous condition and also when dissolved in carbon tetrachloride even at 15 atmospheres pressure. He has calculated the heat necessary for activation and compared it with the total black body radiation at temperatures from 20 to 100 deg. C. At the higher temperature there is not enough radiant energy to produce the actual activation observed. These facts are unfavorable to the radiation hypothesis.

OTHER SECTIONS

Among the excellent papers given at other sectional meetings was one presented by Frank B. Dains of the University of Kansas before the section of Historical and Philological Sciences entitled "Applied Chemistry in Prehistoric and Classical Times." Chemical information was current in considerable amount about 2,000 years ago, but remained without much development until the time of Paracelsus, 1,400 years later. Chemistry is said to begin when copper and tin were mixed together in certain proportions by weight to make bronze, but really began when ores were first smelted to produce metals, or even before, when fire was discovered—or perhaps when man or animal first breathed, or perhaps, in Biblical terms, In the beginning, when God created the universe. Investigations in the valley of the Nile revealed a complete plant equipped with crushers, concentrating tables and cupels for producing metallic gold. Mercury was derived from artificial HgS about 1000 B.C.

Iron was probably first produced in Asia Minor. The Romans had blast furnaces similar in shape to the present-day furnaces but the metal was not completely melted. The mass was alternately heated and hammered to produce the crude metal.

Zinc and tin were made about the time of Paracelsus. Lead was used in Rome for piping water, for coffins and for household utensils. Copper and antimony were known in antiquity, as were red and yellow sulphides of arsenic. The historical development of the Mediterranean nations was in direct proportion to the development of their technical arts.

While it is well to study the literature for the history of chemistry, even more may be gleaned by making analyses of ancient products. Such work reveals the ancients' knowledge of indigo and alizarin dyes. Analyses of ancient glasses and ceramic ware may throw new light on their work. Historical research, then, should look to the analytic methods.

British Chemical Industry

(FROM OUR LONDON CORRESPONDENT)

London, Dec. 13, 1920.

THE chemical trade is, as usual at this time of the year, inclined to be slow, but the slackness has been accentuated by the adverse conditions prevailing in the cotton, paper, leather and other trades. Heavy chemicals are maintaining their price well in spite of foreign competition and in most cases are still far above the actual cost of manufacture.

DYESTUFFS BILL APPROVED BY PARLIAMENT

The dominant feature of the past month has been the dyestuffs campaign, culminating in a partly agreed bill which, like nearly all British safeguards and expedients, will, it is hoped, save the industry literally at the eleventh hour. Under the terms of the bill the importation, subject to a system of licenses, of all synthetic organic dyestuffs and colors and of intermediates used in their manufacture is forbidden for a period of ten years. The Board of Trade is the licensing authority and is to act under the guidance of an advisory committee comprising five users, three manufacturers and three members of the public. The merchant is apparently left out in the cold, but will derive comfort from the fact that the act does not apply to goods for re-export.

Apart from the natural doubts and misgivings with which this last-minute compromise has been received by the cotton trade and other users, many important sections of the chemical industry are greatly troubled in regard to the possibility of a very wide interpretation of the term "organic intermediate products." Some of the products which may fall within this category may have only a restricted use for dyestuffs and the like as compared with their consumption in the chemical and allied industries as a whole. The infant fine chemical trade in particular, which in the past manufactured completely only a small proportion of the goods sold, seems to be particularly affected and efforts are again being made—probably too late—to put this industry also on an economically satisfactory basis.

BRITISH CELLULOSE Co.'s \$1,000,000 DEFICIT

As foreshadowed in these notes of September and October last, the facts and figures presented at the second annual meeting of the British Cellulose Co. held last month are not encouraging. The change over from war to peace conditions has proved a very slow business and for its future prosperity the company seems to rely mainly upon the success of its artificial silk processes. The deficit is quite comprehensible in view of the fact that production has hardly commenced, but even now there seems no prospect of achieving the production originally promised, although the chairman stated that with a one-ton-per-day plant in commercial operation the loss in trading would cease. The problem of dyeing cellulose acetate silk satisfactorily under all circumstances does not yet appear to have been solved, but this is perhaps only a matter of time and experience. Meanwhile much stress is laid upon its special insulating properties, which are stated to be several times greater than those of natural silk. The general feeling seems to be that the cellulose acetate industry will ultimately be firmly established, but meanwhile the enor-

mous value—about \$7,000,000—placed upon good will and patents is having a deterrent effect upon the average investor and it certainly seems difficult to justify.

FAILURE OF INJUNCTION AGAINST BRUNNER, MOND

It will be remembered that the proposal of the directors of Brunner, Mond & Co., Ltd., to devote \$400,000 in aid of research was negatived at the annual meeting by a show of hands, but it was subsequently confirmed at a special meeting called for that purpose. A shareholder endeavored by process of law to oppose this decision on the ground that the directors had exceeded the powers conferred upon them by the articles of association of the company. Most of the large companies and corporations in this country have realized that money spent on scientific research and for the benefit of the chemical industry generally may be relied upon to pay good dividends and an adverse decision would have been most unfortunate. Moreover, the appeal for \$2,000,000, which is now to be launched for the establishment of a central home for the leading chemical societies and for an ambitious scheme of chemical publications was obviously dependent in some measure upon the support and generosity of the large chemical firms. It remains to be seen whether the legality of a donation to such purposes will also be called into question.

WAVE POWER TRANSMISSION

This novel form of transmission of energy was mentioned in a recent note (see CHEM. & MET. ENG., Nov. 10, 1920, p. 913). The details of this invention are difficult to describe in a short note and possibly the following supplementary particulars may therefore be welcome. If we imagine two cylinders fitted with plungers and connected together by a long pipe completely filled with water, this represents the simplest form of wave transmission. If one of the plungers is now moved rapidly up and down, it will set up at each downward stroke harmonic waves of compressed water, which, traveling along the pipe at high speed, will exert their energy on the plunger at the far end and if there is a suitable resistance to the movement of that plunger, a simple synchronous reciprocating motion will be produced. The two cylinders in their developed form are the wave generator and wave motor respectively of the previous note on this subject, but of course the actual development of this harmonic series of impulses into actual practical use is a more complicated matter than the above statement. The main underlying principle involved is really the fact that water is compressible. If a piston is forced under pressure into a pipe 1 in. in diameter and 500 ft. long by about $\frac{1}{4}$ in. in thickness, closed at the far end, the decrease in the volume of the water due to its being compressed is about seventeen times as great as the increase in volume due to the expansion of the pipe line under pressure. The net result is that the piston would enter the containing pipe for a distance of about 11 in. The resulting power wave when this principle is applied in suitable machinery enables practical use to be made of this harmonic motion, which offers an excellent analogy in many ways to alternating current practice in that their laws, formulas and conceptions are very nearly interchangeable. Readers who are more closely interested should write to W. H. Dorman & Co., Ltd., Stafford, England, who would no doubt be glad to give them full particulars.

Current Events

in the Chemical and Metallurgical Industries

Tariff Commission's Surveys of the Chemical Industries

When the Ways and Means Committee held its hearings on chemicals Jan. 6, 7 and 8 in Washington it had at its disposal comprehensive information regarding the complicated and extremely technical tariff problems of the chemical industry. This information was prepared by the United States Tariff Commission in the form of reports known as "Tariff Information Surveys," each of which presents, without suggestion of tariff policy or rates of duty, the main facts and figures pertinent to tariff legislation.

In general the survey follows a standardized form, consisting of a description of the article; uses to which it is put; methods and processes of its manufacture; notable divergences between American and foreign methods of production; the nature and source of its raw materials, and statistical data concerning domestic production, imports and exports, prices, and costs of production, as far as are obtainable, in the United States and in foreign countries.

Schedule A of the tariff act—chemicals, oils and paints—consists of seventy paragraphs, many of which contain provisions for several different products. In some cases the Tariff Commission prepared a single survey to cover a whole paragraph in the tariff act; in other cases, where a paragraph enumerates several unrelated articles, a separate survey was prepared for each article.

The hundred or more surveys of the chemical industry have been grouped into nineteen pamphlets, each of which has been published by the Ways and Means Committee of the House of Representatives, from whom they can be obtained on request.

1. "Acids of Paragraph 1 and Related Materials," includes surveys dealing with boric, citric, formic, gallic, lactic, oxalic, pyrogallie, tannic and tartaric acids, and all other acids and acid anhydrides not specially provided for in that section.

2. "The Wood Chemical Industry," includes surveys dealing with acetic anhydride, acetone, formaldehyde, acetic acid, wood alcohol, calcium acetate, charcoal, and tar and pitch from wood.

3. Paragraphs 4 to 9 inclusive. This includes aluminum and ammonium compounds, egg albumen, copaiba, Peru, tolu and other balsams, as well as the general provision in paragraph 5 for "all chemical and medicinal compounds, preparations, mixtures and salts, and combinations thereof not specially provided for in this section."

4. "Barytes, Barium Chemicals, and Lithopone," includes all of the barium salts in paragraph 10, crude barytes, ground barytes and blanc-fixe in paragraph 51, and lithopone in paragraph 60.

5. Paragraphs 11 to 17 inclusive. This includes blacking of all kinds, bleaching powder, caffeine and tea waste, mercurial preparations, chalk, and chemical and medicinal compounds containing alcohol or imported in capsules, pills, ampoules, etc. Liquid chlorine, whiting and paris white are also discussed in this pamphlet.

6. Paragraphs 18 to 26 inclusive. This includes chloral hydrate, salol, phenolphthalein, aspirin, thymol and other medicinals, chloroform, carbon tetrachloride, cobalt oxide, collodion and pyroxylin plastics, and coloring for brandy, wine, etc. Sulphur chloride is also discussed in connection with the surveys of chloroform and carbon tetrachloride.

7. "Botanical Drugs." This consists of a general survey of the crude botanical drug industry, whose products are dutiable under paragraph 27 or free under paragraph 477, and in addition there have been included the surveys of ergot, paragraph 28, and of the ethers and esters dutiable under paragraph 29.

8. "Tanning Materials and Natural Dyes." This includes all natural tanning materials and vegetable dyes, such as sumac, logwood and other dyewood extracts, chlorophyll and saffron of paragraphs 30 and 31. The following paragraphs from the free list are also discussed in this connection: 399, 455, 469, 475, 492, 536, 538, 553, 564, 618, 624, 630, 634 and 639.

9. Paragraphs 32 to 38 inclusive. This includes surveys of fusel oil, butyl alcohol, gelatine and glue, glycerine, camphor, gum arabic, dextrine and other gums, inks and ink powders, iodine, iodoform and potassium iodide.

10. Paragraphs 39 to 43 inclusive. This includes surveys of buchu leaves, coca leaves, gentian, licorice and sarsaparilla roots, magnesia and magnesium compounds, and menthol.

11. "Animal and Vegetable Oils." This includes all of the fish and animal oils of paragraph 44 and the expressed vegetable oils of paragraph 45. In addition the following oils, free of duty under paragraph 561, are discussed: Chinese nut oil, coconut oil, cod and cod liver oil, cottonseed oil, palm and palm kernel oil, perilla and soya bean oil.

12. "Essential and Distilled Oils." This includes surveys of all essential oils enumerated in paragraph 46, and, in addition, the following essential oils from the free list: Cajeput, ichthyol and juglandium.

13. "Opium." This includes the surveys of opium, cocaine and related alkaloids.

14. "Perfumery, Cosmetics and Toilet Preparations." This includes perfumery, cosmetics and toilet preparations under paragraph 48, and the natural and synthetic perfume materials under paragraph 49; also healing and court plasters under paragraph 50.

15. "Paints and Pigments." This includes all of the surveys dealing with paints and pigments in paragraphs 51 to 63 inclusive, with the exception of barytes, blanc-fixe and lithopone, which have been discussed under paragraph 10.

16. "Potassium Compounds." This includes the surveys of potash and the potassium salts, dutiable under paragraph 64, or free of duty under paragraph 580.

17. Paragraphs 65 to 66. This includes the surveys of salts and compounds of bismuth, gold, platinum, silver, tin, etc.; also the surveys of soaps, dutiable under paragraph 66.

18. "Sodium Compounds." This includes all the sodium salts, dutiable under paragraph 67 or free of duty under paragraph 605; also potassium prussiates, potassium nitrate, potassium chromate and bichromate, dutiable under paragraph 64; chromic acid and silicic acid, free of duty under paragraph 387; chromium hydroxide, paragraph 449; calcium nitrate, paragraph 440; potassium nitrate, crude, and potassium cyanide under paragraph 580.

19. Paragraphs 68 to 70, inclusive. This includes surveys of sponges, talc and soapstone, vanillin, vanilla and tonka beans.

American Engineering Council Assumes Activities of Former Engineering Council

On Jan. 1, 1921, American Engineering Council of the Federated American Engineering Societies assumed the continuation of such activities as have been conducted for the past three and one-half years by Engineering Council of the United Engineering Society. This transfer of activities was made effective by the action of Engineering Council on Dec. 16 in recommending to United Engineering Society that Engineering Council be discontinued. Subsequently United Engineering Society amended its bylaws so as to disestablish Engineering Council.

Symposiums on Drying and Filtration Planned

For the Rochester meeting of the American Chemical Society the division of industrial and engineering chemistry plans to have a symposium on drying. Plans for the program are in charge of the committee now being formed under the chairmanship of Charles O. Lavett of the Buffalo Foundry & Machine Company of Buffalo, N. Y. Those interested in this symposium should communicate their suggestions to the chairman of the committee.

On the occasion of the fall meeting, in New York City, the industrial division program will include a similar symposium on the subject of filtration. The chairman and committee in charge of this program have not yet been selected, but further arrangements will probably be perfected in the near future, as the secretary of the division, Dr. H. E. Howe of the National Research Council, has the matter actively in charge at present.

International Chamber Committee Organized

The American committee to represent in this country the International Chamber of Commerce has fully organized and held its first meeting in New York City on Jan. 6. This agency is the direct representative and point of contact in the United States with the International Chamber of Commerce, which has its headquarters in Paris. Chemical, metallurgical and other engineering interests are represented on the board by the following gentlemen, among others: Herbert C. Hoover, representing Federated American Engineering Societies; Thomas S. Grasselli, Grasselli Chemical Co.; E. A. S. Clark, Consolidated Steel Corporation; A. C. Bedford, Standard Oil Co.; C. F. Kelley, Anaconda Copper Mining Co.; E. G. Miner, Pfaudler Co.; William H. Nichols, General Chemical Co.; Thomas A. O'Donnell, American Petroleum Institute; John J. Raskob, Dupont Co.; Charles M. Schwab, Bethlehem Steel Corporation; Charles A. Stone, American International Corporation; E. P. Thomas, U. S. Steel Products Co.

Nitrate Plant Controversy Grips Senate and House

The nitrate plants at Muscle Shoals, the proposed United States Fixed Nitrogen Corporation and the Wilson dam have come in for extended discussion in Congress during the past two weeks. The Nitrogen Corporation bill became the unfinished business in the Senate after Senator Underwood, the Democratic leader, had threatened to delay the Republican legislative program unless the bill were taken up. In the House the nitrate plant controversy was precipitated by the failure of the Appropriations Committee to provide funds for the continuation of the work on the Wilson dam.

Division of opinion on the matter, however, was not along party lines. The Democrats are not a unit for it, nor are the Republicans uniformly against it. In fact, Representative Mann, of Illinois, one of the Republican leaders, proved to be an effective champion in favor of continuing the work. Opinion in the House is evenly divided, as is indicated by the close vote on the first test of strength, when 125 votes were cast to override the committee, against 132 in support of the committee's position.

An unexpected development in the Nitrogen Corporation discussion came when Senator Wadsworth, of New York, submitted amendments withdrawing the corporation entirely from the jurisdiction of the War Depart-

ment and proposing that it be placed under the Treasury Department, because he believes "soldiers ought not to be running a business concern." Another amendment by Senator Wadsworth proposes material changes in the plan for capitalization. He would give the corporation the power to sell common stock in any amount not to exceed \$20,000,000. Another amendment by Senator Wadsworth limits the activities of the corporation to the manufacture of ammonium nitrate, ammonium sulphate and cyanamide from atmospheric nitrogen.

In submitting his estimates to Congress the Secretary of War requested \$10,000,000 for the continuation of the work on the Wilson dam. This item was entirely omitted by the committee in framing the sundry civil bill on the ground that the policy with respect to carrying forward the project had not been worked out.

In the course of his remarks Mr. Good, chairman of the Committee on Appropriations, said: "I can but feel that a great blunder was made when the American Cyanamid Co. was given a free hand in the making of the plans for building Plant No. 2, which is the large plant. I have forgotten whether it is the American Cyanamid Co. or the American Chemical Co., but the two were in very close relation. One of them prepared the plans and constructed this plant. One or the other of these companies, which have been working very closely together, has the patent rights for the Haber process. The Haber process is covered by a great many letters patent and these companies, or one of them, hold the letters patent. True, the basic patent was granted seventeen years ago, but when this company was given the power to make the plans for this plant it made its plans for the manufacturing plant to fit in with its patents. So every unit of the building, every piece of construction, everything that was done was in order to turn out nitrates at Plant No. 2 under the Haber process, which is covered by these patents, and the company receives royalties on every ton produced—\$5 a ton royalty on cyanamide and \$10.11 a ton on nitrates of ammonia. The royalties under the present contract for 100,000 tons of nitrates of ammonia, the estimated annual production, would be \$2,200,000."

At another point in his remarks Mr. Good said: "We will have to become accustomed to some higher Government salaries if the Government is going to engage in this kind of enterprise. You cannot compete with the American Cyanamid Co. in the manufacture of fertilizer and nitrate if you are going to have \$2,500-a-year men or \$5,000-a-year men to manage the plant when a competing company pays from five to ten times such sums for their managers in order to secure the best talent available. You must apply to Government affairs the same business principles that a business man adopts in connection with his affairs if you want the Government to succeed in business."

Among the champions for the continuance of the project was Representative Garrett, of Tennessee. At one point in his address he stated that some chemists are of the opinion that eventually the Haber process will be developed to a point when nitrates can be fixed at a cheaper cost by that method than by the cyanamide process, but he continued: "We must bear in mind that however hopeful gentlemen may be of the eventual development of the Haber process it still is speculative in this country and the cost of production by it necessarily is speculative."

At another point in his remarks Mr. Garrett expressed the opinion that it is not possible to dispose

of the nitrate plant to private parties at any price that would approach, even remotely, a just return to the Government. "So far as I know," he continued, "no one ever has believed that it is possible for private capital to construct this dam economically."

Representative Graham, of Illinois, deprecated the spirit of "let the Government do it." So far as the nitrate plant controversy is concerned, he said, the parting of the ways has been reached. "We must either embark on the national management and manufacture of fertilizers or we must take the other road which leads to individual initiative and enterprise." He expressed the opinion that the real purpose of the power development is to erect at Muscle Shoals, at Government expense, a water-power project for the development of that part of the country. "I am opposed to junking this plant," he declared. "I am equally opposed to the Government running it, if there is any other way to do it. I favor its operation by private capital. Plant No. 1 is a failure, always has been a failure and always will be a failure. At the time it was built they knew considerable about the Haber process, which, by the way, is the coming process in this country. The method to be used in Plant No. 2 is obsolescent. Inside of ten years it probably will not be used at all. The Haber process is a simpler process. It has grown by leaps and bounds during the war. The Haber patents are open to the use of any man. I am informed privately that there are at present organizations in the United States, with great capital behind them, organized for the manufacture of synthetic ammonia by the Haber process. If the United States goes into the business that industry perishes, as do all others related to the production of nitrates from the atmosphere. How can any privately owned industry compete with the United States Government?"

Representative Almon, of Alabama, said: "Who is opposing the proposition that the Government should operate this plant? No one has come out in the open in opposition except Mr. Washburn, who operates a similar, but much smaller, plant at Niagara Falls, on the Canadian side. This plant would be his competitor."

Representative Mann, in concluding his speech, said: "Shall we scrap a plant simply because we feel resentment at its cost? Shall we throw away an opportunity because we do not like the men who have created it? Shall we waste the thing that we have because we do not like the methods that have been followed? We ought to rise above that. We ought to be willing to continue the work which is of benefit to the country and which utilizes Nature's power to draw from the air this plant food."

National Public Works Association Final Report

The final report of the National Public Works Association has just been completed by C. T. Chenery, secretary, dated Dec. 30. American Engineering Council will take over the work of this association, together with the work of Engineering Council, the first of the calendar year. This report of the public works activities is, therefore, its final summary of association affairs.

In addition to the effort to obtain passage of a bill to create a department of public works, known as the Jones-Reavis measure, this association has been active in support of the resolution recently passed by Congress known as the Smoot-Reavis resolution, providing

a Congressional commission for the investigation of the need of and basis for reorganization of the executive departments. In fact, the Public Works Association can properly be credited with having been one of the most influential agencies in obtaining the early passage of this resolution, which has just become a law through the failure of the President to act on the measure within ten days following its submission to him, which ten days expired December 30. It is hoped by those interested in the public works department that the need for it will be quickly demonstrated and that the first measure approved by the commission will be this particular part of Government reorganization.

Comments on Dye Development

A brief historical summary of the history of the dye industry in the United States, showing its growth from a small unit in the general industrial machine to a tremendous factor in the manufacturing life of the country, was given at the December meeting by Dr. C. G. Derick, in charge of the Research Laboratory of the National Aniline & Chemical Co., Buffalo, N. Y., before the Rochester Section of the American Chemical Society, in the Eastman Building of the University of Rochester. In addition to his historical remarks Dr. Derick also touched upon the problems confronting the industry at present.

Before 1914 about 70 per cent of the annual output of 400,000,000 lb. of dyestuffs was produced in Germany, no other one country producing as much as 10 per cent. England produced about 6½ per cent, France 5½, the United States 5, and Switzerland about 8 per cent. Scientific research can be considered the backbone of the German monopoly. However, had there not been a small industry in this country since 1870 the situation would have been much worse. In speaking of the history of the dye industry in this country Dr. Derick said that back in 1869 out on Buffalo Creek J. F. Schoelfkopf started a small factory. The same building served as stable, factory, laboratory, office and restaurant. The beginning was small and the difficulties were many, such as the Buffalo River rising and floating away part of the factory. This small concern was dependent upon Germany for its apparatus and the intermediates from which the dyes were made. Competition was keen with Germany, which held the monopoly and intended to keep it.

About twenty years ago, however, Schoelfkopf worked out a new black dye and patented it. It proved to be one of the most popular dyes. When he tried to get patents in other countries, however, Germany stepped in and said she had known about it for a long time. Then started one of the hardest fights the dye industry in this country ever had. Germany, seeing she was losing ground, tried then to compromise, divide up markets, etc. There was great rejoicing when the first carload of dye left the small Schoelfkopf factory. The value of an American patent backed by American law cannot be overestimated.

In 1914 Schoelfkopf thought the war would not last very long and having a large supply of intermediates on hand made up dyes and sold them at good profit. But it soon became evident that the war would not soon be over and the dye industry would suffer. Schoelfkopf made contracts with his older men to work out new dyes and share in the profits. In May, 1916, the old building was torn down, in August the research

chemists, Dr. Derick being in charge, went into the new building, and by Christmas of that same year twenty buildings were in operation and putting out from 60 to 70 per cent of the total consumption of this country. This wonderful work was made possible through the thirty-five years of research, experience and hard work. The contractors also deserve much credit for putting up the buildings in record time.

Dr. Derick went on to speak of the work involved in research, which may be divided into two classes—the exploratory function and the developmental function. In the United States about 99 per cent of the research has been along the latter line and this cannot go on; more work must be done in exploration. The research work in dyes must develop the dyestuffs, patent them and work out methods for qualitative analysis. Twenty per cent of the total business was dyes the constitution and components of which were unknown. The great problem then was to work out these unknowns, and this has now been done; there is not an important German secret in the dye industry that has not been solved in the laboratory, but some have not been as yet developed. Another phase of the work is the realization of the fundamental relation between constitution and color. The principal coal-tar products used in the making of dyes are benzene, toluene, naphthalene and anthracene.

The problems of the research man which must be solved in the laboratory are the materials that enter into the specifications, methods of analysis to back up the specifications, study of operations, study of variables and methods of control. The hazard study involving explosives likely to be produced and the effect of materials on the health of the workers is most important.

After the work leaves the research chemist it goes to the research engineering division, where apparatus is decided upon and estimates are made. Then the process goes to the factory and is worked out by a special set of workers under the supervision of the research chemist long enough to get accurate records of cost, etc.

Special difficulties that must be met and overcome are the effect of shutdowns of engineering service, such as of steam or electricity at an important point, which may result in an explosion, death of workers, or spoiled products. Other difficulties are the destructive action of bacteria and yeast to the finished dyestuffs. The patent situation must be continuously watched.

General Fries Advocates Plan to Stimulate Inventive Initiative in C.W.S.

General A. A. Fries, the head of the Chemical Warfare Service, states that some plan of systematic handling of inventions by Government employees is very necessary in the Chemical Warfare Service. As it is there is great need for stimulating inventive initiative and effort. He believes this applies to the whole Government service, but it is of unusual importance in his organization, where the field is so new. Under present conditions, he points out, many Government employees leave the service to develop their ideas so that they may participate in its benefits. Greater incentive must be given Government research workers if maximum progress is made in such matters as the development of war gases, General Fries said. He characterized the attitude of some of the concerns opposing such a plan as being narrow and an inheritance from the days of the alchemist, when all chemical research was hedged about with deep secrecy.

Industrial Investigations in Universities

On Friday evening, Jan. 7, the New York Section of the American Chemical Society was addressed by two prominent professors.

Dr. Warren K. Lewis reported that the new co-operative system established at Mass. Inst. of Tech. is proving highly advantageous both to the graduate students and to the score of industries represented. Co-operative students are chosen competitively on the basis of scholarship shown in their undergraduate work, reliability, personality and ability. A great amount of plant philosophy is imparted to the students and industry is saved the trouble of training raw recruits.

Drs. Ralph H. McKee and E. E. Lyder presented a very comprehensive report of their investigations on the pyrolysis of shale kerogens. The primary decomposition product at about 400 deg. C. was shown to be viscid tarry hydrocarbons which break down under destructive distillation (at 500 to 600 deg. C.) to form secondary products—oils, vapors, gases and free carbon. The investigations also included the determination of physical constants which may be of importance in process design.

Personal

H. FOSTER BAIN has been recommended by the Secretary of the Interior for the directorship of the Bureau of Mines. Dr. F. G. Cottrell's resignation has been accepted by Secretary Payne, effective Jan. 1. Dr. Cottrell has resigned to become chairman of the Division of Chemistry and Chemical Technology of the National Research Council. Both Mr. Bain and Dr. Cottrell will enter upon their new duties immediately. Mr. Bain during the war was assistant director of the Bureau of Mines and is widely known for his work as a consulting mining engineer and as a geologist. He has just returned from a trip to the Far East, where he made examinations of mining properties in ten countries.

Dr. C. B. CLEVENGER has resigned as instructor in the department of chemistry, University of Wisconsin, Madison, Wis., to accept a professorship of agricultural chemistry and head of the department of chemistry of the Manitoba Agricultural College, Winnipeg, Canada.

WILL H. COGHILL of the U. S. Bureau of Mines has gone to Platteville, Wis., to study the sludge problem in the Wisconsin zinc district.

W. C. GRAHAM, formerly of the Great Western Sugar Co. and now having his own business in the Coronado Bldg., Denver, Col., left New York on Jan. 8 to be away for several months on a special mission for the South Porto Rico Sugar Co.

Dr. RALPH E. HALL, formerly of the Geophysical Laboratory of the Carnegie Institution, Washington, D. C., has resigned from the Firestone Rubber Co., Akron, Ohio, to accept a position with the Koppers Co. of Pittsburgh, Pa.

FREDERICK A. HARVEY has resigned from the Semet-Solvay Co. to become technical assistant to the president of the United States Refractories Corporation, which prior to Jan. 1 was known as the Mt. Union Refractories Co.

ELLWOOD HENDRICK, consulting editor of CHEMICAL & METALLURGICAL ENGINEERING, lectured before the Polytechnic Section of the American Institute of the City of New York on Jan. 3 on "The Sense of Smell."

E. L. JORGENSEN, formerly general superintendent of reduction for the Chile Exploration Co. at Chuquicamata, Chile, has after fifteen years with Guggenheim Companies opened an office as consulting engineer in Suite 1429, 150 Nassau St., New York City.

CHARLES H. MILLER of Auburn, N. Y., has started a chemical and physical laboratory for the McIntosh & Seymour Corporation, maker of Diesel engines. The materials used in the manufacture, as well as the coal, oil, etc., will be tested chemically and physically.

PROF. JAMES F. NORRIS has been elected to the chairmanship of the committee in charge of the C. M. Warren Fund of the American Academy of Arts and Sciences, in place of Prof. H. P. Talbot, resigned. The income from the fund is available for the "encouragement and advancement of research in the science or field of chemistry," and may be used to provide the materials required for such investigations or assistant in their execution. The committee will be glad to receive and consider requests for grants from this fund. They should be addressed to Prof. James F. Norris, Massachusetts Institute of Technology, Cambridge, Mass.

A. A. RACKOFF, Wilkinsburg, Pa., is now specializing on special steel works and labor-saving machinery, teeming devices and coke-oven accessories.

Dr. L. I. SHAW lectured before the Franklin Institute Jan. 6, 1921, on "Smoke and Incendiary Material."

DR. EDGAR FAHS SMITH has been elected president of the American Chemical Society for the year 1921.

At the College of the City of New York Prof. HERBERT R. MOODY has been appointed professor of chemical engineering within the department of chemistry; Asst. Prof. W. L. PRAGER has been promoted to an associate professorship and JOSEPH A. BABOR has been promoted to an instructorship.

The Royal Society of England has awarded the Coply medal to H. T. BROWN for his work on the chemistry of carbohydrates, on the assimilation of atmospheric carbon dioxide by leaves, and on gaseous diffusion through small apertures; the Rumford medal to Lord RAYLEIGH for researches into the properties of gases at high vacua; the Davy medal to C. T. HEYCOCK for his work in physical chemistry, especially on the composition and constitution of alloys, and the Hughes medal to Prof. O. N. RICHARDSON for his work in experimental physics on the passage of electricity through gases, and especially for those relating to the electrons from hot bodies, which he has termed "thermionies."

The British Institution of Mining and Metallurgy has awarded its gold medal to Sir THOMAS KIRKE ROSE in recognition of his eminent services in the advancement of metallurgical science with special reference to the metallurgy of gold.

Current Market Reports

The Chemical and Allied Industrial Markets

New York, Jan. 10, 1921.

Large inquiries were not numerous during the past week in the chemical market but the situation showed signs of recovering from the effects of the recent holidays and producers seemed confident of a slow but gradual improvement in business during the rest of the month. Buyers are generally holding off and seem to be waiting for someone to start the ball rolling. There seems to be little doubt that should someone break the ice consumers will come into the market in force. Prices generally continue weak and subject to shading among leading dealers. Producers are still holding quotations well up to their recently quoted levels for contracts over 1921 in spite of the lack of any considerable business.

Resale *bichromate of soda* was offered at 9½c. per lb., with some sellers, however, asking 9¼c. Trade conditions were not very active and buyers appeared content to await new developments in the market before operating. Offerings were not heavy and February shipments were held at about 1c. premium over spot goods. *Solid caustic soda* opened steady on the spot market with sales recorded at

\$3.75@3.80 per 100 lb. This was the general quotation named for domestic and export use and the tone appeared quite steady. No change was noted in contract prices and producers continued to quote 3¼c. per lb., basis 60 per cent works, for forward shipments.

Small lots of American *cyanide of soda* were held at 30c. per lb. by dealers. The French variety sold at prices ranging from 21c to 24c. per lb. Some high-test German was on the market at 23c. English material was rather scarce on spot and was held at 24@26c. per lb. Moderate business in *formaldehyde* was booked at 18½c. per lb. spot in barrels. The market is quoted quite steady at this figure, with small lots held as high as 19@19½c. Wide differences of opinion were held as to the *arsenic* market. Some lots of white material were said to have sold as low as 9c. per lb. c.i.f. New York for immediate shipment from Japan. Other holders were quoting 10c. per lb. Spot quotations ranged from 10½ to 11½c., according to quantity and sellers.

The market on *caustic potash* remained in an unsettled condition. Imported material 88-92 per cent strength caused further weakness to the spot market. Consumers were unwilling to enter the market in spite of the bargain prices which were offered through second hands. Prices ranging from 14c. to 16c. per lb. for imported seemed to represent a fair low mark for this material. Domestic producers' quotations were far above these figures.

Producers on American *chlorate of potash* continued to quote 18c. per lb. for goods in warehouse. Second hands offered imported goods as low as 11c. per lb., with practically no response from leading match and powder factories. Demand of late has generally been of a very limited nature. There were some sellers of *nitrite of soda* as low as 6c. per lb. for spot goods and quotations were heard from 6¼ to 6½c. per lb. The inside figure was said to be for round lots and was not general in the open market. The low figure compares with 14c. per lb., the initial price last January, and with the high point touched, 60c. per lb. last March. Resale *bleaching powder* was quoted by dealers at 2½@2¾c. per lb. Some fair sales were recorded in small drums at intermediate prices. The inquiry appeared to be moderate, although enough supplies were around to meet all requirements. A feature of the market was the persistent demand for carload lots of light *soda ash* in single bags at the works. Producers seemed well sold up for immediate business and dealers were not anxious to quote the present market. Spot goods have been taken off the market during the past few days and the general undertone appeared quite steady. Prices ranged from \$1.90 to \$2.10 per 100 lb. for single bags. Barrels were held at 5c. per 100 lb. premium.

COAL-TAR MARKET

The new year has revealed nothing startling and most factors reported a light demand for small quantities of staple products that have a routine call. Inquiries from European sources showed an increase and seemed to indicate that there is a real need for some items. Opinions from different producers, on the other hand, were that these inquiries of the moment are in the nature of feelers trying out the market. Crude materials are quiet and prices are quotably unchanged from previous reports. While there has been no heavy demand for *anthracene*, there is nevertheless a healthy look and the steady developments along the vat dyes are keeping producers rather light on available material. Manufacturers of intermediates are steady in their views and dealers are also more conservative than they have been as to prices. What little is offered on the open market is held on a firmer basis than heretofore.

Small lot trading of *aniline oil* constituted about the extent of business during the week. The market seemed more steady around 23@25c. per lb., although supplies were easy in most quarters. The market on *aniline salt* showed little change from the former quiet stand. There were no new developments featuring the trade and prices held along the regular range from 27c. to 30c. per lb. Reports from most quarters stated that the market for *dinitrobenzene* is quiet. Supplies were said to be available in moderate volume on a basis of 27@30c. per lb. Consumers of *orthotoluidine* are showing little interest at this time. Producers are steady

in their views around 25@30c. per lb., with fair supplies available. While there were some resale lots of *paranitraniline* floating around the market, the quantity is not large and a firmer view is held as to prices, which range from 93c. to \$1 per lb.

WAXES

The wax market in the past few weeks has been exceptionally quiet, with only small orders from domestic consumers noted. The inquiry for *crude beeswax* was moderate but trading in the refined material was very dull. The spot market for *Carnauba wax* saw no change in action, but a fair amount of interest was shown in shipments. No. 3 North Country was held at 20@25c. per lb., with futures available at about 18c. per lb. A limited inquiry was in evidence for *Japan wax*, and with spot material not pressing the market prices remained unchanged at 19@20c. per lb. The market for *scale wax* was unsettled, with offerings in some directions of a liberal nature. *Crude wax* 124 m.p. was available at 6½c. per lb., with carload lots a trifle under the figure. Refined 133 m.p. wax was offered at 10½c., with no new business noted.

COAL-TAR PRODUCTS MARKET FOR 1920

The sensational rise of the coal-tar, intermediate and dyestuff markets was directly due to the wave of export business that flooded the country immediately after the severe slump during the latter part of 1919. It was generally supposed that Germany had accumulated a tremendous surplus stock of dyes during the war and the entire world was waiting to see whether this condition was a reality. Rumors were current that German interests were about ready to ship in continuous quantities to the outside markets dyes of every description, and as a result consumers were narrowing their orders to the barest necessities. Stocks were reduced to await the time when prices and quality would reach pre-war levels by the Germans in their efforts to once more rehabilitate themselves to their former commercial supremacy.

During the later months of 1919 there were no signs of any importations of dyes and buyers became pessimistic as to the truth about these hoarded stocks. This was an impetus for live buying and immediately orders were noted in large volume for American-made material. Prices soared to their highest peak during the early months of 1920. With this sudden turn in the trend of business it became evident that American manufacturers were not entirely prepared to meet this overwhelming demand. General conditions in other lines prevented any expansion in the industry, and as stocks became depleted with the demand greater than the supply prices fluctuated. Speculation became the order of the day here and abroad. Buyers were paying fabulous prices in order to get what little there was on the spot market. Principal among export buyers were Japan and the Far East countries. Japan, as was noticed in the chemical industry, speculated blindly. Material was bought at any price and it soon became evident that stocks had accumulated which were sufficient to cover her requirements over a period of a few years. The result was inevitable. A chaotic condition arose in Japan when banks began to call their loans on speculative holdings and also to refuse any additional credits. In order to save themselves the Japanese turned from the buying end to the selling. Large holdings were brought back to the American market at sacrifice prices. Prices began to break rapidly and domestic consumers, who had been willfully neglected during the foreign rush, took the upper hand. Stocks moved sluggishly in view of the fact that material was offered at bargain prices. The market became demoralized through these forces and it is in this condition that the coal-tar and intermediate markets find themselves at the turn of the year.

There were many factors together with the enormous export demand that hindered any additional production. The coal strike reduced supplies of all crude-tar manufacturers. Shortage of coal forced practically all of the byproduct coke plants to work on greatly reduced schedules. The car shortage, railroad inefficiency and the unusually hard winter

COMPARATIVE PRICES OF COAL-TAR PRODUCTS. JANUARY-DECEMBER, 1920

added to the difficulties of American producers. It became evident that some material had to be imported. Naphthalene led among speculators and soon an oversupply followed the rapid slump in business. Large holders began to offer their purchases for resale at prices far below manufacturers' quotations. The same condition held true on all other coal-tar products.

The 1921 prospect for business seems very indefinite and will remain so until some settlement is reached on the tariff question. No point is of such crucial significance to the industry at the present time as the passage of suitable protective measures by Congress. The present scale of operation as well as the expert supervision required causes enormous expenses and makes it necessary for the American manufacturer to charge more for his product than the German. Some definite action in this matter will immediately set the industry on a firm basis and development work which will follow will be one of the greatest factors in reducing the cost of American products to the consumers. Prices will probably rise without any resumption of new business, as present stocks have been generally reduced to a minimum. It is problematical whether this will occur during the first quarter. The only logical solution is that the rebound will be gradual and that business will increase until a normal volume of trade is reached. Prices are much lower now than at the beginning of 1920 and in some cases are even below the cost of production. Any inequalities will undoubtedly be removed in the immediate future and legitimate prices will be set forth which will include legitimate profits.

The St. Louis Market

St. Louis, Jan. 5, 1921.

A more cheerful tone has been evident in the heavy chemical market during the last week. Producers report many domestic consumers renewing contracts at the price levels established around the middle of December. Shipments on contracts have picked up appreciably since the first of the year also. Although spot sales have not increased to any great extent the number of inquiries has increased. One helping factor is the almost complete absence from the market of small distressed lots of heavy chemicals.

Quotations have changed in only one instance, and producers are manipulating their production in such a manner that their stocks of heavy chemicals will not accumulate beyond control. In a few instances a quickening demand has found supply low.

Demand for the 98 deg. *sulphuric acid* is still slow and the price has dropped to \$24 per ton f.o.b. works from the previous quotation of \$25 per ton. The 66 deg. acid continues in strong demand, the greater portion of the production going to the oil refineries. Quotations are stable at \$20@21 per ton and 1½c. per lb. in carboys, carload lots. The demand for the 60 deg. sulphuric acid has shown flashes of activity in the last few days and the current price is \$16 per ton and 1½c. per lb. in carboys. *Oleum* has shared in this increased activity, producers reporting inquiries good, although orders have picked up only slightly. It is being offered at \$28.50 per ton.

Producers report that users are calling more actively for *muriatic acid*. Stocks were not large and prices are holding firmly at \$25 per ton in bulk and 1¾@2c. per lb.

Sodium bisulphate is quiet, but there are no very large lots to offer and the greater part of the production is being shipped on contract. The nominal quotation is \$7@\$8 per ton.

Zinc chloride is not in exceptionally strong demand, but there has been no further decrease in quotations. It is being offered at \$4.15 per 100 lb.

The *nitric acid* market is quiet and quotations are \$7 per 100 lb. for the 36 deg. test and \$10 per 100 lb. for 42 leg. Quotations on standard mixed acid are unchanged.

The Chicago Market

Chicago, Jan. 5, 1921.

A very definite tendency toward a stronger market is felt on all sides since the turn of the calendar. This has not been evidenced by any marked price advances nor by increased demand, but rather by the very definite decrease in the volume of supplies in the stocks of second hands. The trend of the past few months has been toward the elimination of the speculator and the vest-pocket trader, who were so largely responsible for the extreme height to which prices rose last year. With their activity reduced to a minimum and with markets largely in the hands of producers, prices are bound to be more stable and to be based on actual worth.

With consumption going on at a day-to-day rate and with production materially retarded, no oversupply in any item seems probable. From this it is deduced that while prices may not necessarily be at their bottom level they are very near to it. Dealers and manufacturers are a unit in expressing the opinion that business during the coming season is going to be good.

HEAVY CHEMICALS

Little action, but prices firmly held, in general, has been the story of the past two weeks. In the soda group only routine orders are being placed, but spot stocks seem to be getting low. *Soda ash* offerings are at \$2 per 100 lb. now, against \$1.85 ten days ago. All supplies are firmly held at the quoted price. *Caustic soda* has been moving in good volume, orders averaging small but running to a good total. Today's quotation is \$3.85@\$4.15 per 100 lb. *Sal soda*, at \$2.25 per 100 lb., is in routine demand only. No large stocks of *sodium bichromate* are to be found and prices are held at 12@13c. per lb., with demand steady.

The *alcohol* market is still in a bad way. Production of *methyl* grade has been seriously curtailed and with the gradual depletion of resale stocks current quotations of \$1.80 per gal. for 97 per cent should represent about the bottom of the market. *Ethyl* grade, owing to the uncertainty of future production costs, is uncertain as regards supply. At present the market is quiet at \$5.15 per gal. for 190 proof. Supply of *denatured* is still greatly in excess of demand, and quoted price of 80@90c. indicated the wide range of price offerings.

Glycerine remains at a very low ebb, buyers showing no interest and holders of stock apparently being content to hold. The c.p. grade, held at 19c. per lb. f.o.b. works, is exciting no interest and saponification grade is offered at 12c., with but little business resulting. *Quicksilver*, quoted at \$43@\$45 per flask, is said to be cheaper than production cost, in spite of which demand remains light.

Acids are facing a weak market. Price range does not seem to mean much to consumers, who are content to limit purchases to their day-to-day requirements. Current quotations, most of which can be shaded, are: 66 deg. *sulphuric*, \$24 per ton; 36 deg. *nitric*, \$6.50@\$6.75 per 100 lb.; *muriatic*, 18 deg., \$1.85@\$2 per 100 lb.; *acetic*, glacial, 10½@11½c. per lb., 56 per cent, 5½@5¾c. per lb. Production of all acids is being curtailed.

VEGETABLE OILS

Continued weakness is noted in this line, small volume of transactions and lowering prices being the order of the day. Quotations are largely nominal as large stocks are still in second hands and most any offer will be made to induce sales. *Linseed oil*, unchanged in quotation, could actually be bought at 76c. per gal. in car lots. *Cottonseed oil*, quoted at 6c. per lb. f.o.b. point of production, is not only below cost but is also lower than the appraisement value upon which bank loans were made a few months ago. Actual transactions are few. *Corn oil*, firmed up in price by reduced production, is held at 7c. per lb. f.o.b. Chicago, but no reports are heard of any sales of importance. *Coconut oil*, in spite of rumored impending shortage, excites no interest at the current price from local warehouse of 12½c. per lb. for crude and 15c. for deodorized.

NAVAL STORES

Owing to the widespread depression in the various industries which use naval stores prices are held at low levels and but little real business is being done. Very recent improvements in foreign exchange rates may make possible increased export business, which has been negligible for some weeks. Current quotation on *turpentine* in barrels by the carload f.o.b. Chicago is \$1.09½ per gal.; in drums it is 6c. lower. Better grades of *rosin* are quoted at \$10.25 per 100 lb., and lower grades at \$9.90@\$10. Distilled *pine oil*, under fair demand, remains unchanged.

COAL-TAR PRODUCTS

The dye trade shows every indication that stocks in consumers' hands are low, which promises well for the future. The recently reported resumption of work in numerous textile plants, although on a reduced scale, is another favorable factor. Great interest is shown in the action to be taken by Congress in placing a protective tariff on products of the coal-tar industry. Quotations on crudes, while firm, are largely nominal, as transactions are few. *Phenol* is offered at 10@12c. per lb., sales at any figure being light. Spot stocks are reported as diminishing. *Toluol* shows a similar wide price range, offerings ranging from 32c. to 36c. per gal. *Benzene*, 90 per cent, is quoted at 33c. per gal., and *naphthalene* in both ball and flake form at 9@10c. per lb. All coal-tar acids are reported as very quiet, current quotations being purely nominal. *Benzoic* is offered at 65c. per lb. for technical grade and 70c. for U.S.P.; *picric* at about 35c.; *salicylic* at 36@38c. for U.S.P.

The Iron and Steel Market

Pittsburgh, Pa., Jan. 7, 1921.

Independent pipe mills have reduced their prices to the Steel Corporation level. The movement was inaugurated by the Republic Iron & Steel Co., which distributed new list prices under date of Dec. 31, other independents following in short order, some lists being dated Jan. 1 and others Jan. 3. The difference in dates is immaterial, they merely fixing the time for readjustment of prices on current shipments against old contracts, and Jan. 1 was not a shipping date.

Pipe was the only important steel mill product requiring readjustment from the advanced independent market, and thus the return of the independent steel market to the Steel Corporation or Industrial Board level was completed, without a day to spare, within the limits of the calendar year. The real flight of the independent market had only begun in 1920. There were some advanced prices secured late in 1919, but at the time the advances were regarded as simply involving a premium for early delivery. Later, or in 1920,

the independents would not sell for any delivery except at their advanced prices, while formerly they simply refused to sell for extended delivery at all.

OPERATIONS

The trend in independent mill operations is downward, but there has been no general closing. Many mills are closed but others are operating at rates up to perhaps 50 or 60 per cent of capacity. The general average among independents is perhaps not over 20 per cent. The Carnegie Steel Co. has been producing ingots at fully 96 per cent of rated capacity, while the National Tube Co. is running full. These two subsidiaries have 53 per cent of the Steel Corporation's total ingot capacity. The Illinois Steel Co. is reported to be operating at 85 per cent. The general average of the Steel Corporation is probably about 92 per cent.

If the independents are operating at 20 per cent and the Steel Corporation at 92 per cent, the general average for the industry is about 52 per cent of capacity, or about 65 per cent of the average rate during the period of heavy demand, the first nine months of 1920. In that period the mills averaged only 80 per cent, being held down by shortages of cars and fuel, and in spots a little labor shortage.

Predictions that were being made in December that there would be an "improvement" in the steel trade immediately after the turn of the year need not be taken seriously. There could be an increase in buying without its offsetting the exhaustion of old contracts, and no signs even of that are now seen. With steel production and shipments at 65 per cent of the former rate one may doubt whether the present rate can be maintained, for it is not reasonable to suppose that steel consumption has decreased by only 35 per cent. Indeed, some steel producers candidly state that they know some of the steel they are shipping is not going into actual consumption, although their customers are willing to receive it. The trend of the next few weeks, therefore, is likely to be a downward trend in production. It is from a rate lower than the present that recovery is to start.

PRICE PROSPECTS

A common prediction was that almost as soon as the independents reduced their prices to the Steel Corporation level they would begin to shade the new prices. The prediction did not reckon with present conditions, when no new business of importance is developing. At the moment the chief recourse of the independents, in endeavoring to secure business, would be to take business from the Steel Corporation. That would be difficult if not impossible, but in any event would not be attempted, for obvious reasons.

The present prospect seems to be, therefore, that prices will remain as they are for a time, with occasional shading, no doubt, until some substantial volume of new business develops. With a light operation costs are high, but a little additional operation would not mend matters a great deal. The lowest prices will probably be seen when there is hope that by cutting prices a reasonably full operation can be secured. Meanwhile costs will be coming down. There is scarcely any doubt that eventually, and before there is an upturn in prices, there will be a somewhat lower level than now obtains, but that is not for the immediate future.

While there have been some wage reductions among the independent steel producers the movement is very far from general. It appears to be the common impression that the present is not an appropriate time. The independent mills are largely idle in any event. As to the Steel Corporation, there is no expectation that it will take any action in the matter of wages for quite a while.

PIG IRON

The prediction made last week as to bessemer and basic pig iron prices is borne out, as there are furnace offerings this week at \$3 decline, \$32 for bessemer and \$30 for basic at valley furnaces. Foundry is not clearly defined, but seems quotable at \$33, a decline of \$2. There is no inquiry, and the few furnaces still in blast contemplate going out as they complete orders or make up enough iron to take care of orders in hand. No unsold pig iron is being made.

Acetic, glacial, 99½ per cent, carboys, 100 lbs.	10.50 - 11.00	11.25 - 11.50
Boric, crystals.....lb.	14½ - 15	15½ - 16
Boric, powder.....lb.	15½ - 16½	17 - 18
Citric.....lb.		50 - 52
Hydrochloric.....100 lb.	1.85 - 2.25	2.75 - 3.00
Hydrofluoric, 52 per cent.....lb.	15 - 16	16½ - 18
Lactic, 44 per cent tech.....lb.	10 - 11	11½ - 12
Lactic, 22 per cent tech.....lb.	04½ - 05½	06 - 07
Molybdic, C. P.....lb.	4.00 - 4.50	4.50 - 5.00
Muriatic, 20 deg. (see hydrochloric).....lb.		
Nitric, 40 deg.....lb.	07 - 07½	08 - 08½
Nitric, 42 deg.....lb.	08½ - 09	09½ - 10
Oxalic, crystals.....lb.	18½ - 18½	19 - 20
Phosphoric, Ortho, 50 per cent solution.....lb.	18 - 18½	18½ - 19
Picric.....lb.	28 - 35	40 - 50
Pyrogallol, resublimed.....lb.		2.30 - 2.40
Sulphuric, 60 deg., tank cars.....ton		14.00 - 15.00
Sulphuric, 60 deg., drums.....ton		
Sulphuric, 66 deg., tank cars.....ton	18.00 - 19.00	
Sulphuric, 66 deg., drums.....ton	21.00 - 22.00	22.50 - 23.00
Sulphuric, 66 deg., carboys.....ton		
Sulphuric, fuming, 20 per cent (oleum) tank cars.....ton	23.00 - 24.00	
Sulphuric, fuming, 20 per cent (oleum) drums.....ton	25.00 - 26.00	26.50 - 27.00
Sulphuric, fuming, 20 per cent (oleum) carboys.....ton	32.00 - 35.00	40.00 -
Tannic, U. S. P.....lb.		1.30 - 1.35
Tannic (tech.).....lb.	48 - 50	51 - 52
Tartaric, crystals.....lb.		33 - 35
Tungstic, per lb. of WO.....lb.		1.20 - 1.40
Alcohol, Ethyl (nominal).....gal.		5.25 - 5.50
Alcohol, Methyl (see methanol).....gal.		
Alcohol, denatur ed, 188 proof.....gal.		70 - 72
Alcohol, denatur ed, 190 proof.....gal.		75 - 77
Alum, ammonia lump.....lb.	04½ - 04½	05 - 05½
Alum, potash lump.....lb.	05½ - 06	06½ - 07
Alum, chrome lump.....lb.	13 - 13½	14 - 14½
Aluminum sulphate, commercial.....lb.	02½ - 03	03½ - 03½
Aluminum sulphate, iron free.....lb.	03½ - 03½	04 - 04½
Aqua ammonia, 26 deg., drums (750 lb.).....lb.	06½ - 07	07½ - 08½
Ammonia, anhydrous, cyl. (100-150 lb.).....lb.	30 - 32	33 - 35
Ammonium carbonate, powder.....lb.	14 - 14½	14½ - 15
Ammonium chloride, granular (white salamoniac) (nominal).....lb.	10½ - 11	11½ - 11½
Ammonium chloride, granular (gray salamoniac).....lb.	09½ - 09½	10 - 10½
Ammonium nitrate.....lb.	09 - 09½	10 - 10½
Ammonium sulphate.....lb.	03½ - 03½	04 - 04½
Amylacetate.....gal.		4.25 - 4.50
Amylacetate tech.....gal.		3.50 - 3.75
Arsenic oxide, lumps (white arsenic).....lb.	10½ - 11	11½ - 11½
Arsenic, sulphide, powdered (red arsenic).....lb.	15 - 15½	15 - 15
Barium chloride.....ton	75.00 - 80.00	85.00 - 90.00
Barium dioxide (peroxide).....lb.	24 - 25	26 - 27
Barium nitrate.....lb.	10 - 10½	10½ - 11
Barium sulphate (precip.) (blanc fixe).....lb.	04½ - 05	05½ - 06
Bleaching powder (see calc. hypochlorite).....lb.		
Blue vitriol (see copper sulphate).....lb.		
Borax (see sodium borate).....lb.		
Brimstone (see sulphur, roll).....lb.		
Bromine.....lb.	50 - 52	54 - 56
Calcium acetate.....100 lbs.	2.00 - 2.05	
Calcium carbide.....lb.	04 - 04½	04 - 05
Calcium chloride, fused, lump.....ton	27.00 - 29.00	30.00 - 32.00
Calcium chloride, granulated.....lb.	02 - 02½	02½ - 03
Calcium hypochlorite (bleach'g powder).....lb.	02½ - 03	03½ - 03½
Calcium peroxide.....lb.		1.25 - 1.30
Calcium phosphate, monobasic.....lb.		16 - 18
Calcium sulphate, pure.....lb.		05 - 05
Camphor.....lb.		88 - 90
Carbon bisulphide.....lb.	08 - 08½	09 - 09½
Carbon tetrachloride, drums.....lb.	11 - 11½	11½ - 12
Carbonyl chloride (phosgene).....lb.		60 - 75
Caustic potash (see potassium hydroxide).....lb.		
Caustic soda (see sodium hydroxide).....lb.		
Chlorine, gas, liquid-cylinders (100 lb.).....lb.	09 - 09½	10 - 10½
Chloroform.....lb.		43 - 50
Cobalt oxide.....lb.		3.90 - 4.00
Copper as (see iron sulphate).....lb.		
Copper carbonate, green precipitate.....lb.	22 - 22½	24 - 25
Copper cyanide.....lb.		40 - 50
Copper sulphate, crystals.....lb.	06½ - 06	07 - 07½
Cream of tartar (see potassium bitartrate).....lb.		
Epsom salt (see magnesium sulphate).....lb.		
Ethyl Acetate Com. 85%.....gal.		1.05 - 1.10
Ethyl Acetate pure (acetic ether 98% to 100%).....gal.		
Formaldehyde, 40 per cent.....lb.	18½ - 18	19 - 19½
Fusel oil, ref.....gal.		3.50 - 3.60
Fusel oil, crude.....gal.		2.75 - 3.00
Glauber's salt (see sodium sulphate).....lb.		
Glycerine, C. P. drums extra.....lb.		20 - 21
Iodine, resublimed.....lb.		3.85 - 4.00
Iron oxide, red.....lb.		10 - 20
Iron sulphate (copperas).....100 lb.	1.50 - 1.75	2.00 - 2.25
Lead acetate, normal.....lb.		14½ - 16
Lead arsenate (paste).....lb.	13 - 14	14½ - 15
Lead nitrate, crystals.....lb.		90 - 1.00
Litharge.....lb.	10 - 10½	10½ - 11½
Lithium carbonate.....lb.		1.50 -
Magnesium carbonate, technical.....lb.	10½ - 11	11½ - 12
Magnesium sulphate, U. S. P.....100 lb.	3.00 - 3.25	
Magnesium sulphate, commercial.....100 lb.		1.50 - 1.75
Methanol, 95%.....gal.		1.60 - 1.65
Methanol, pure.....gal.		1.85 - 1.95
Nickel salt, double.....lb.		12 - 12½
Nickel salt, single.....lb.		13 - 13½
Phosgene (see carbonyl chloride).....lb.		
Phosphorus, red.....lb.	45 - 46	47 - 50
Phosphorus, yellow.....lb.		35 - 37
Potassium bichromate.....lb.	17 - 17½	17½ - 18

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar)..... lb.	\$.38 — .40	\$0.38 — \$0.40
Potassium bromide, granular..... lb.	.35 — .40	.35 — .40
Potassium carbonate, U. S. P..... lb.	.11 — .11½	.11 — .12
Potassium carbonate, crude..... lb.	.11 — .12	.13 — .18
Potassium chlorate, crystals..... lb.	.14 — .14½	.15 — .16
Potassium cyanide..... lb.	75.00 — 80.00	3.00 — 3.20
Potassium hydroxide (caustic potash)..... lb.	11½ — 12	12½ — 13
Potassium iodide..... lb.	.60 — .63	.65 — .70
Potassium nitrate..... lb.	.60 — .62	.63 — .65
Potassium permanganate..... lb.	.31 — .31½	.32 — .33
Potassium prussiate, red..... lb.	\$225.00 — 230.00	
Potassium prussiate, yellow..... lb.		
Potassium sulphate (powdered)..... ton		
Rochelle salts (see sodium potas tartrate)		
Salammoniac (see ammonium chloride)		
Sal soda (see sodium carbonate)		
Salt cake..... ton	40.00 — 45.00	
Silver cyanide..... oz.	1.25 — 1.45	
Silver nitrate..... oz.	.43 — .45	
Soda ash, light..... 100 lb.	1.90 — 2.00	2.10 — 2.30
Soda ash, dense..... 100 lb.	2.30 — 2.50	2.75 — 3.00
Sodium acetate..... lb.	.05½ — .05¾	.06 — .06½
Sodium bicarbonate..... 100 lb.	2.45 — 2.60	2.65 — 3.00
Sodium bichromate..... lb.	.09¼ — .09½	.09½ — .10
Sodium bisulphate (nitre cake)..... ton	7.00 — 7.50	8.00 — 11.00
Sodium bisulphite powdered, U.S.P..... lb.	.06½ — .07	.07 — .08
Sodium borate (borax)..... lb.	.07 — .07½	.07½ — .08
Sodium carbonate (sal soda)..... 100 lb.	2.00 — 2.25	2.50 — 2.75
Sodium chl rate..... lb.	.10 — .10½	.10½ — .11
Sodium cyanide, 96-98 per cent..... lb.	.21 — .23	.24 — .30
Sodium fluoride..... lb.	.17 — .17½	.17½ — .18½
Sodium hydroxide (caustic soda)..... 100 lb.	3.75 — 4.00	4.25 — 4.35
Sodium hyposulphite..... lb.	.03 — .04	.03 — .04
Sodium nitrate..... 100 lb.	2.85 — 3.00	3.00 — 3.00
Sodium nitrite..... lb.	.06 — .06½	.06½ — .07
Sodium peroxide, powdered..... lb.	.30 — .31	.32 — .34
Sodium phosphate, dibasic..... lb.	.03½ — .04½	.04½ — .05
Sodium potassium tartrate (Rochelle salts) lb.	.33 — .35	.33 — .35
Sodium prussiate, yellow..... lb.	.17 — .17½	.17½ — .18
Sodium silicate, solution (40 deg.)..... lb.	.01½ — .01¾	.02 — .02½
Sodium silicate, solution (60 deg.)..... lb.	.03 — .03½	.03½ — .04
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1.75 — 2.00	2.25 — 2.50
Sodium sulphide, crystal, 60-62 per cent (conc.) lb.	.06 — .06½	.07 — .07½
Sodium sulphite, crystals..... lb.	.04 — .04½	.04½ — .05
Strontium nitrate, powdered..... lb.	.20 — .20½	.21 — .22
Sulphur chl ride, red..... lb.	.08 — .09	.10 — .10½
Sulphur, crude..... ton	16.00 — 20.00	
Sulphur dioxide, liquid, cylinders..... lb.	.09 — .10	.10 — .12
Sulphur (sublimed), flour..... 100 lb.		3.70 — 4.35
Sulphur, roll (brimstone)..... 100 lb.		3.40 — 3.90
Tin bichloride, 50 per cent..... lb.	.18 — .19	
Tin oxide..... lb.		.50 — .51
Zinc carbonate, precipitate..... lb.	.16 — .18	.19 — .20
Zinc chloride, gran..... lb.	.11½ — .12	.12½ — .13
Zinc cyanide..... lb.	.45 — .49	.50 — .60
Zinc dust..... lb.	.12 — .13	.13½ — .14
Zinc oxide, XX..... lb.	.10 — .10½	.11 — .11½
Zinc sulphate..... lb.	.03½ — .03¾	.04 — .06

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.10 — \$1.15
Alpha-naphthol, refined..... lb.	1.45 — 1.50
Alpha-naphthylamine..... lb.	.40 — .44
Aniline oil, drums extra..... lb.	.23 — .25
Aniline salts..... lb.	.27 — .30
Anthracene, 80% in drums (100 lb.)..... lb.	.85 — 1.00
Benzaldehyde (f.f.c.)..... lb.	2.00 — 2.10
Benzidine, base..... lb.	1.00 — 1.10
Benzidine sulphate..... lb.	.85 — .90
Benzoic acid, U.S.P..... lb.	.70 — .75
Benzoate of soda, U.S.P..... lb.	.75 — .85
Benzene, pure, water-white, in drums (100 gal.)..... gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)..... gal.	.28 — .32
Benzyl chloride, 95-97%, refined..... lb.	.35 — .40
Benzyl chloride, tech..... lb.	.25 — .35
Beta-naphthol benzoate..... lb.	3.50 — 4.00
Beta-naphthol, sublimed..... lb.	.75 — .80
Beta-naphthol, tech (nominal)..... lb.	.38 — .42
Beta-naphthylamine, sublimed..... lb.	2.25 — 2.40
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 — .18
Ortho-cresol, in drums (100 lb.)..... lb.	.23 — .25
Cresylic acid, 97-99%, straw color, in drums..... gal.	.95 — 1.00
Cresylic acid, 95-97%, dark, in drums..... gal.	.90 — .95
Cresylic acid, 50%, first quality, drums..... gal.	.65 — .75
Dichlorobenzene..... lb.	.06½ — .15
Diethylaniline..... lb.	1.35 — 1.40
Dimethylaniline..... lb.	.65 — .90
Dinitrobenzene..... lb.	.27 — .30
Dinitrochlorobenzene..... lb.	.25 — .30
Dinitronaphthalene..... lb.	.40 — .45
Dinitrophenol..... lb.	.40 — .45
Dinitrotoluene..... lb.	.27 — .30
Dip oil, 25%, tar acids, car lots, in drums..... gal.	.38 — .40
Diphenylamine..... lb.	.70 — .75
H-acid..... lb.	1.40 — 1.55
Meta-phenylenediamine..... lb.	1.25 — 1.30
Monochlorobenzene..... lb.	.15 — .16
Monoethylaniline..... lb.	1.75 — 2.25
Naphthalene crushed, in bbls. (250 lb.)..... lb.	.08 — .08½
Naphthalene, flake..... lb.	.08 — .08½
Naphthalene, balls..... lb.	.09 — .09½
Naphthionic acid, crude..... lb.	.70 — .75
Nitrobenzene..... lb.	.12 — .15
Nitro-naphthalene..... lb.	.40 — .50
Nitro-toluene..... lb.	.18 — .25
Ortho-amidophenol..... lb.	3.20 — 3.75
Ortho-dichlor-benzene..... lb.	.15 — .20
Ortho-nitro-phenol..... lb.	.75 — .80
Ortho-nitro-toluene..... lb.	.23 — .30
Ortho-toluidine..... lb.	.25 — .30
Para-amidophenol, base..... lb.	1.90 — 2.00
Para-amidophenol, HCl..... lb.	2.20 — 2.25

Para-dichlorobenzene..... lb.	.10 — .15
Paranitroaniline..... lb.	.93 — 1.00
Para-nitrotoluene..... lb.	1.25 — 1.40
Para-phenylenediamine..... lb.	2.20 — 2.35
Para-toluidine..... lb.	1.70 — 1.80
Phthalic anhydride..... lb.	.60 — .70
Phenol, U. S. P., drums (dest.), (240 lb.)..... lb.	.09 — .10
Pyridine..... gal.	2.00 — 3.50
Resorcinol, technical..... lb.	2.75 — 2.80
Resorcinol, pure..... lb.	3.60 — 3.80
Salicylic acid, tech., in bbls. (110 lb.)..... lb.	.30 — .32
Salicylic acid, U. S. P..... lb.	.33 — .35
Salol..... lb.	.85 — .95
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.28 — .32
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.16 — .18
Sulphanilic acid, crude..... lb.	.32 — .35
Tolidine..... lb.	1.35 — 1.40
Toluidine, mixed..... lb.	.45 — .55
Toluene, in tank cars..... gal.	.30 — .32
Toluene, in drums..... gal.	.33 — .35
Xylidines, drums, 100 gal..... lb.	.45 — .50
Xylene, pure, in drums..... gal.	.42 — .45
Xylene, pure, in tank cars..... gal.	.45 — .45
Xylene, commercial, in drums, 100 gal..... gal.	.33 — .35
Xylene, commercial, in tank cars..... gal.	.30 — .30

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark..... lb.	\$0.24 — \$0.26
Beeswax, refined, light..... lb.	.27 — .28
Beeswax, white pure..... lb.	.35 — .40
Carnauba, No. 1..... lb.	.85 — .90
Carnauba, No. 2, North Country..... lb.	.40 — .42
Carnauba, No. 3, North Country..... lb.	.20 — .25
Japan..... lb.	.19 — .20
Montan, crude..... lb.	.07 — .08
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.06½ — .06¾
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.06½ — .06¾
Paraffine waxes, refined, 118-120 m.p..... lb.	.07 — .07½
Paraffine waxes, refined, 125 m.p..... lb.	.07½ — .08
Paraffine waxes, refined, 128-130 m.p..... lb.	.08½ — .09
Paraffine waxes, refined, 133-135 m.p..... lb.	.10½ — .11
Paraffine waxes, refined, 135-137 m.p..... lb.	.11 — .12
Stearic acid, single pressed..... lb.	.14½ — .15
Stearic acid, double pressed..... lb.	.15½ — .15¾
Stearic acid, triple pressed..... lb.	.15½ — .16½

Flotation Oils

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr. 0.930-0.940..... gal.	\$1.90
Pine oil, pure, dest. dist..... gal.	1.50
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.48
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75
Pine tar, ref., thin, sp.gr. 1.080-1.960..... gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970..... gal.	1.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990..... gal.	.35
Pinewood creosote, ref..... gal.	.52

Naval Stores

The following prices are f.o.b. New York for carload lots.

Rosin B-D, bbl..... 280 lb.	\$8.75 —
Rosin E-I..... 280 lb.	8.75 —
Rosin K-N..... 280 lb.	8.75 —
Rosin W. G.-W. W..... 280 lb.	9.00 —
Wood rosin, bbl..... 280 lb.	9.00 —
Spirits of turpentine..... gal.	.75 —
Wood turpentine, steam dist..... gal.	.73 —
Wood turpentine, dest. dist..... gal.	.73 —
Pine tar pitch, bbl..... 200 lb.	8.50 —
Tar, kiln burned, bbl. (500 lb.)..... bbl.	15.00 —
Retort tar, bbl..... 500 lb.	15.00 —
Rosin oil, first run..... gal.	.60 —
Rosin oil, second run..... gal.	.62 —
Rosin oil, third run..... gal.	.75 —

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.41
70-72 deg., steel bbls. (85 lb.)..... gal.	.39
68-70 deg., steel bbls. (85 lb.)..... gal.	.38
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.30

Crude Rubber

Para-Upriver fine..... lb.	\$0.18½ — \$0.19
Upriver coarse..... lb.	.14 — .14½
Upriver caucho ball..... lb.	.14½ — .14¾
Plantation—First latex crepe..... lb.	.17 —
Ribbed smoked sheets..... lb.	.16½ —
Brown crepe, thin, clean..... lb.	.16 —
Amber crepe No. 1..... lb.	.17 —

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.10 — \$0.11½
Castor oil, AA, in bbls..... lb.	.12 — .13
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.08½ — .09
Cocanut oil, Ceylon grade, in bbls..... lb.	.13 — .13½
Cocanut oil, Cochín grade, in bbls..... lb.	.13½ — .14
Corn oil, crude, in bbls..... lb.	.09 — .09½
Cottonseed oil, crude (f. o. b. mill)..... lb.	.06 — .07
Cottonseed oil, summer yellow..... lb.	.08½ — .08¾
Cottonseed oil, winter yellow..... lb.	.09 — .09½
Linseed oil, raw, car lots (domestic)..... gal.	.77 — .79
Linseed oil, raw, tank cars (domestic)..... gal.	.73 — .74
Linseed oil, boiled, car lots (domestic)..... gal.	.78 — .80

Olive oil, commercial.....	gal.	2.60	—	2.70
Palm, Lagos.....	lb.	.07	—	.08
Palm, Niger.....	lb.	.07	—	.08
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.07	—	.07
Peanut oil, refined, in bbls.....	lb.	.13	—	.13
Rapeseed oil, refined in bbls.....	gal.	1.10	—	1.15
Rapeseed oil, blown, in bbls.....	gal.	1.20	—	1.25
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.08	—	.09
Soya bean oil, tank cars, f.o.b., Pacific coast....	lb.	.06	—	.07

FISH

Light pressed Menhaden.....	gal.	\$0.53	—	\$0.55
Yellow bleached Menhaden.....	gal.	.55	—	.58
White bleached Menhaden.....	gal.	.57	—	.60
Blown Menhaden.....	gal.	1.00	—	

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Connecticut

DANBURY—The Beaver Brook Paper Mills, Inc., Beaver Brook St., plans to build a 1-story, 75x150-ft. addition to its manufacturing plant. Private plans.

Indiana

MARION—The Standard Glass Co. plans to build a 1-story glass factory. Estimated cost, \$75,000. Private plans.

TERRE HAUTE—The Union Hospital will receive bids after Feb. 1 for the construction of a 6-story, 80x120-ft. hospital on North Eighth St. Estimated cost, \$337,000. Johnson, Miller & Miller, archts.

Iowa

COLLINS—The Bd. Educ. will soon award the contract for the construction of a 2-story, 69x109-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$150,000. B. L. Mead, secy. T. Thorson, Forest City, archt.

Massachusetts

LEOMINSTER—The Viscoloid Co. will build a 1-story, 20x95-ft. addition to its plant for the manufacture of viscoloid sheetings. Estimated cost, \$15,000.

Michigan

GLADSTONE—The Bd. Educ. will receive bids until March 1 for the construction of a 2-story, 120x130-ft. junior high school on Main St. A chemical laboratory will be installed in same. Estimated cost, \$140,000. G. Arutzen, Escanaba, archt. and engr.

Montana

MILES CITY—The Custer Co. Free High School will soon award the contract for the construction of a 3-story high school. A chemical laboratory will be installed in same. Estimated cost, \$400,000. G. F. Ingersoll, clk. W. A. Dedrick, Billings, archt. Noted Jan. 5.

New York

BROOKLYN—R. Embers, 209 King St., has awarded the contract for the construction of a 1-story, 60x100-ft. foundry on Richards St., to T. Drysdale, 250 Baltic St. Estimated cost, \$35,000.

North Dakota

MANDAN—The city is having plans prepared for the construction of a filtration plant and new reservoir or repairs to the present one. Estimated cost, \$150,000.

Ohio

COLUMBUS—The Ohio State University plans to build 13 buildings to include a chemistry building. Estimated cost, \$4,000,000.

SALEM—B. M. French, city engr., plans to construct a new building to include a filtering and settling basin with complete pumping and purification plant. Estimated cost, \$800,000.

SANDUSKY—The Hard Color Products Co., South Columbus Ave., has awarded the contract for the construction of a 1-story factory for repair work, to H. K. Ferguson Co., 6223 Euclid Ave., Cleveland. Estimated cost, \$50,000.

Oklahoma

LINCOLNVILLE—The Natl. Tripoli Co., Chamber of Commerce Bldg., Joplin, Mo., will receive bids until Jan. 25 for the construction of a 2-story factory to have a capacity of 100 tons. Estimated cost, \$130,000. G. A. Smith, pres.

Pennsylvania

PHILADELPHIA—The Amer. Eng. Co., Spexiva St. and Wheatshaf Lane, has awarded the contract for the construction of a 1-story, 50x100-ft. foundry and ma-

chine shop to the Austin Co., Bulletin Bldg. Estimated cost, \$25,000. Noted Dec. 29.

PHILADELPHIA—H. T. Potts & Co., Inc., 316 North Third St., has awarded the contract for the construction of a 1-story foundry on D and Erie Sts., to W. Steel & Sons Co., Sixteenth and Arch Sts. Estimated cost, over \$15,000.

South Dakota

EGAN—The Bd. Educ. is having plans prepared for the construction of a 1- or 2-story consolidated school. A chemical laboratory will be installed in same. Estimated cost, \$150,000. Schumacher & Finkelhor, 316 Paulton Blk., Sioux Falls, archts.

Texas

AUSTIN—The city plans an election to vote on \$20,000 bonds to construct improvements to the sewage disposal plant. Address W. D. Yett, Mayor, or C. E. Leonard, engr.

Wisconsin

ANTIGO—The Bd. Educ., c/o R. A. Brandt, is having plans prepared for the construction of a 2-story, 127x225-ft. junior high school on Main St. A chemical laboratory will be installed in same. Estimated cost, \$250,000. Oppenhammer & Obel, Wausau, archts.

GOODMAN—The School Bd. plans to build a 2-story, 90x125-ft. high and grade school. A chemical laboratory will be installed in same. Estimated cost, \$125,000. E. Tough, 24 East Mifflin St., Madison, archt.

Quebec

MONTREAL EAST—The Royal Duke Oil Co., 157 St. James St., Montreal, will receive bids until Jan. 15 for the construction of a plant for the purification of gasoline distilled, etc. Estimated cost, \$50,000. W. B. Richards & Co., 203 Bernard Ave., W., engr.

Industrial Notes

THE FISHER GOVERNOR Co., Marshalltown, Iowa, has taken over the manufacturing of the O-B regulating valve, formerly made by the Ohio Brass Co. In the future the valve will be known as the Fisher pressure regulating valve.

F. J. RYAN & Co., Franklin Trust Bldg., Philadelphia, are completing the installation of a large electric processing oven at the Thermoid Rubber Co., Trenton, N. J. This equipment is the second large processing equipment built by this company. The chief interest surrounds the possibility of solvent recovery owing to the form of heat used.

THE ELECTRIC FURNACE Co., Alliance, O., is installing a complete automatic heat-treating set at the new plant of the C. H. Wills Co., of Marysville, Mich. The set is designed to treat all kinds of automobile parts and consists of a 200-kw. hardening furnace, a motor operated quench and a 200-kw. drawing furnace. A 200-kw. Baily annealing furnace is being installed at the Springfield plant of the Ohio Steel Foundries Co., and a similar outfit but with 300 kw. electrical capacity has been ordered for export to the Oddehome Steel Corp. of Norway.

THE WISE ELECTRO-SHERARDIZING CORP. has started production at 2326 South Western Ave., Chicago, Ill. This company gives a sherardizing treatment to metal by an electric process as distinguished from the gas process of heating.

THE MEMPHIS IRON & STEEL Co. started operations at the first unit of the new mill recently, and is producing bars and round iron.

THE AUSTIN MACHINERY CORP. of Chicago has established a distributing branch in Memphis, Tenn., for the Arkansas and Tennessee territories. J. M. McCampbell will have charge of the new organization.

THE ELECTRIC FURNACE CONSTRUCTION Co., Philadelphia, announces the starting of a "Greaves-Etchells" electric furnace at the Holmes Foundry Co.'s plant, Port

Huron, Mich., for refining and superheating molten cupola metal. It has been found possible by short-treatment in the electric furnace to increase the fluidity of the metal and to largely eliminate sulphur. The cupola iron contained 0.102 per cent average sulphur, and the finished product showed only 0.023 per cent sulphur. Time taken was about forty minutes. Charges of cold scrap have also been run, consisting of 80 per cent cylinder scrap and 20 per cent iron borings. Sulphur in final product from the cold-melted heat was reduced to 0.013 per cent.

Manufacturers' Catalogs

HOLZ & Co., New York, has issued two new bulletins. No. 11 is on "The Eden-Foster Repeater Impact Testing Machine" for investigating the resistance of steel and other metals to fatigue procured by repeated stresses of small force, and No. 41 is on the "Burrows Defectoscope and Magnetic Analyzer" for the inspection of steel rails, rods, wire, cable and all other steel and iron stock of uniform section. Both booklets are illustrated.

INTERNATIONAL OXYGEN Co., Newark, N. J., calls attention to Bull. No. 61, covering the design, construction and operating characteristics of the I.O.C. system electrolytic oxygen-hydrogen generator type 1,000, which has just been published. The company announces that it will forward copies free of charge to anyone interested in the production of oxygen and hydrogen for industrial purposes.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its annual meeting Feb. 21 to 24, at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting Feb. 14 to 17 in New York City.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

COMMON BRICK MANUFACTURERS' ASSOCIATION OF AMERICA will hold its annual meeting at the Hotel Pennsylvania, New York City, Jan. 31 to Feb. 4.

COMPRESSED GAS MANUFACTURERS' ASSOCIATION will hold its eighth annual meeting, Monday, Jan. 17, at 2 p.m., at the Hotel Astor, New York, and its eighth annual dinner at the same place that evening.

NATIONAL PETROLEUM CONGRESS will meet at the Hotel Baltimore, Kansas City, Mo., March 22 to 25.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF CHEMICAL INDUSTRY holds its Perkin Medal Award Meeting at Rumford Hall, Chemists' Club, New York, on Jan. 14.

THE SEVENTH EXPOSITION OF CHEMICAL INDUSTRIES will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: Jan. 14, Society of Chemical Industry, Perkin Medal award; Feb. 11, American Electrochemical Society, joint meeting with Society of Chemical Industry, American Chemical Society and Société de Chimie Industrielle; March 11, American Chemical Society, Nichols Medal award; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Perkin Medal for Doctor Whitney

THE award of the Perkin Medal to Dr. WILLIS R. WHITNEY, director of the research laboratory of the General Electric Co., will meet with universal approval which will only be heightened by the doctor's generous attempts at self-effacement. He was the unanimous choice of the Committee on Award. Dr. WHITNEY may protest that he cannot graciously accept the medal as a personal tribute and that he shines in the accumulated glory of members of his staff. But even in this recognition of his loyal associates, Dr. WHITNEY'S admirers will find indirect though ample justification for the honor that has come to him. Accepting for the moment his disclaimer to personal achievement, which the record will not sustain, his name is synonymous with one of the first and most successful organizations for industrial and scientific research. This in itself is no light accomplishment, and if Dr. WHITNEY prefers to let his claim to fame rest thereon his friends will still feel that it is quite sufficient to warrant his present recognition.

Senate Muddles The Nitrate Bill

AFTER several weeks of debate on the bill to create the United States Fixed Nitrogen Corporation the Senate passed it in amended form on Jan. 14. It will be recalled that the purpose of this bill was to provide the necessary corporate machinery for federal ownership and operation in the interest of the War Department of the nitrate plants at Muscle Shoals. As the Senate discussion grew in volume the fog in which the entire subject has been enshrouded increased in density until there was little likelihood that the Senate could emerge from it with any intelligent action. One has only to read the debate in the *Congressional Record* for the past few weeks to confirm the forecast which we made months ago when we intimated that on account of the complexity of the subject, the dust created in the course of discussion probably would obscure and defeat the legitimate ends of the bill. The nitrogen question is many-sided. Even if one had to deal only with its economics and technology, the subject would be large enough. But when, as in the present instance, it is so intimately mixed with politics, public and private, there is little hope of intelligent action.

It is true that economic and industrial conditions have changed since the bill was introduced a year ago and it is quite possible that it needed amendment. But such amendments as Senator WADSWORTH introduced on Jan. 4 could have but one purpose and effect—namely, to kill the bill. Their full purport is not evident at this writing, but one of them takes the jurisdiction of the plant out of the War Department and puts it in the Treasury. Another increases the corporation's

financial obligations to the United States by requiring it to issue bonds up to half of the war-time expenditures of the Government in constructing the nitrate plants and for the full value of the hydro-electric installation if and when acquired by the corporation. This has been done in spite of the fact (or maybe in accord with it) that persistent opponents of the bill have testified to Congressional committees that the Plant No. 2 could not possibly be sold for anything like its war-time cost nor even leased on any such basis.

The amendments can scarcely be taken in good faith, because they require the corporation to earn 5 per cent on its securities under penalty of ceasing operations and awaiting further action by Congress. This would kill it in its first year of operation. It would also compel it to operate the plants at the greatest capacity and enter into the stiffest kind of competition with commercial fertilizer manufacturers—something that never was contemplated by any of those who have advocated the control and operation of the plants by the War Department. One of the objections to that control and operation was that the peace-time product of the plants must inevitably compete with certain articles of domestic commerce, and objection was raised to the United States engaging in such competition. The current amendments practically impose upon the corporation the necessity of engaging in such competition, if it is to maintain its existence.

In the consideration of this, as of many other technical subjects with which Congress has to deal, we are repeatedly impressed with the value of the much-maligned "single-track" mind. It is far superior to the "sidetrack" mind which seems to develop in large number and great variety whenever a complicated question is before our national legislature. In the present instance the issues have been so misrepresented, distorted and complicated that the original and legitimate reasons for and purposes of the bill have been lost to sight. Let us keep them clearly in mind. The United States has made a large investment in plants for nitrogen fixation at Muscle Shoals. The Chief of Ordnance is charged with securing and maintaining an adequate supply of munitions for the Army; and at present, as in the past, his only source of nitrate is in a foreign country, Chile. There is no nitrogen-fixation industry now actively functioning in this country, capable of furnishing the Chief of Ordnance with a supply of nitrate in case of emergency. From this point of view and this one alone, CHEMICAL & METALLURGICAL ENGINEERING has seen sufficient justification for the creation of some agency for the utilization of the Muscle Shoals plants by the War Department. Until there is an active nitrogen-fixation industry in this country which can function for the Ordnance Department in case of emergency, just as the steel industry can and does, the Government is justified in controlling so complete an agency for the production of nitrate as the plants at

Muscle Shoals. The purpose of such control and operation is nitrogen preparedness. If the original provisions of S. 3390 will not accomplish this purpose, let us discover and support some other measure that will. In our judgment the bill might as well die as pass in its amended form, because the corporation could not possibly function under the conditions imposed. Let us not forget that the issues involved relate primarily to national welfare. From that viewpoint it is inconceivable that after our war experience we should be guilty of the indefensible folly of dependence on Chile.

Chemists May Become Chemical Ambassadors

THE chemical profession needs more ambassadors in industry. Not chemical politicians, not talkers and salesmen of the chemical idea, but rather ambassadors who, by their action in everyday business relations, individually propagandize the doctrine of technical control of plant operations. The number of men available for this work is large, but few hold to the thought.

Between the two fields of chemical activity—pure research on one hand and betterment of industry on the other—it rests with the individual chemist to choose. Should he decide on the former he is to be congratulated, for all the delights of meandering through the dreamland of technical philosophy, all the honors for original discoveries, all the pleasures of independent thinking and of exploration for new ideas, will be his. The beauty of nature's contour, color and music, and all man-made imitations of these, are formless, achromatic and discordant compared to the joyous travels of the inner scientific mind.

But all cannot follow this beacon light of pure science. The majority must occupy themselves with industry; for industry must eventually support research, that research, in turn, may advance industry. Pure science burdened with sordid matters of money cannot climb the peaks. The great host traveling the industrial highway have, however, one ideal in common—namely, that the chemist may become the top executive with each business organization so he can properly apply the principles of his partner, the research man, to the forwarding of the industry in question.

Accomplishment of this object demands that he seemingly depart far from the ways of theoretical science while inwardly clinging to the ideal. For industry thrives best on practical common-sense sort of procedures. On leaving school after a year or two occupied in a rounding out of the theoretical side of his training, the chemist should enter the production department of his chosen industry and start a new training in common sense. He will learn to appreciate that a large amount of work has been done even by rule-of-thumb methods, and see how he may gradually inculcate technical procedure without disturbing the financial equilibrium of the plant operations. He should never forget that he is the servant of the stockholders, who are vitally interested in cash profits.

Many times a new invention cannot be immediately adopted because of the enormous loss involved in scrapping the equipment of the less remunerative process. If a man were hungry and had only the price of a baking oven, he would not buy the oven but rather spend the money on flour and fuel to make his bread by the open fire. New apparatus is often nice but too expensive. Plain thinking rules industry.

The Opportunist In Research

EXPERIENCED research directors of real achievement condemn the opportunist in research, for such a man will do only that which he sees as promising for increased dividends tomorrow. He cannot see as far ahead as next week and he never thinks of the problems of next year. The condemnation of the opportunist is, indeed, frequent among those who really know how to organize and carry through a research program. On the other hand, the commendation of one who knows how to plan and "gets away with it" is not so frequent, though fully as well deserved. It is a pleasure, therefore, to emphasize examples of successful far-seeing research programs.

One of the most striking examples of this sort recently came about in the work of the research division of a large organic chemical corporation whose name is known throughout America wherever the language of chemists is spoken. This research division had under way for several years a program of investigation for which it had been rather criticized by the management of the company. How the director of research managed under the circumstances to keep the work going is a secret which he alone could tell. But in any event he did so.

The reward of the effort which had been made through several years came in full measure recently. With changing relation between costs of materials, the expense for wages and the margin of profits possible in the plant processes, this corporation found it wholly impracticable to continue upon the war-time basis of plant operation. The directors threw up their hands in horror at the situation. They were virtually helpless when confronted by the new industrial problems. That they were thoroughly terrified by the situation is evident by the fact that they took the initiative in consulting the director of research as to what they should do. Then it was that they learned the purpose of all the research upon which they had previously frowned. They found it possible to abandon the old processes which had previously been financially successful, even to the extent of scrapping equipment and structures on an extensive scale. The new program promises to be even more handsomely successful than the old, simply because the research department had fully worked out through all stages of laboratory and semi-commercial scale the industrial requirements of a new economic situation.

Had this corporation been successful in discouraging the far-sighted research program and had the program of an opportunist been insisted on, it is very doubtful whether the research staff could possibly have answered the appeal when this distressing situation was encountered by the management. Some other organizations, which have not been so sympathetic in research and development work upon a scale suited to long periods of successful plant operation, can only take their losses and hope that their conversion to the newer thought may be sincere and permanent. If they are not converted fully, they can rest assured that they will sooner or later be eliminated from consideration. With conditions which demanded close figuring only the best processes and the most efficient utilization of byproducts and wastes can successfully continue under present conditions in competition with other well-planned and scientifically-controlled business.

Presentation of Perkin Medal to Willis R. Whitney

Addresses Made at the Fourteenth Award of the Perkin Medal by the Society of Chemical Industry—
Personal Remembrances by Elihu Thompson and Arthur D. Little—Presentation by C. F. Chandler—
Acknowledgments and "The Biggest Things in Chemistry" by Willis R. Whitney

THE fourteenth Perkin Medal presentation meeting of the American Section of the Society of Chemical Industry was held in Rumford Hall Friday evening, Jan. 14. In the course of his introductory remarks Sumner R. Church said: "It is my own privilege as chairman of the Medal Committee to state simply that at the meeting when the selection was made there was no word spoken save in unanimity of choice. Since then we have heard no words save of approval and heartfelt pleasure concerning this award. I can testify that Whitney's example has inspired every man in this country who has to do with the direction of chemical research. Whenever he could he gave freely of his time to advise and encourage those who visited him, however slight their claims might be."

TWENTY YEARS OF RESEARCH

Prof. Elihu Thompson gave an excellent review of the work of the General Electric research laboratories, using as an illustration the development of the incandescent lamp. The original carbon filament lamp was not very satisfactory. When operated at a temperature which gave a high ratio of light to energy input, the vapor pressure of carbon was so high that carbon was condensed too rapidly on the bulb. The physical properties of carbon were somewhat improved in the G-E-metallized filament which was the basis of the G-E-M lamp. Tantalum, molybdenum, osmium and tungsten were investigated successively. Coolidge's process for making tungsten ductile so that standardized wires could be drawn is the foundation of the modern incandescent lamp industry.

Biographical Reminiscences

BY ARTHUR D. LITTLE

From the point of view from which I see this audience it is in the main a gathering of young men. To them I am glad to say that years bring their compensation. It is pleasant to be able to remember the fiftieth anniversary of the discovery of mauve, to recall its modest and benign discoverer, to have participated in the festivals which were designed to do him honor and to have shared the desire to perpetuate the memory of that discovery and its momentous consequences by the foundation of the Perkin Medal.

Someone has said that an institution is the elongated shadow of a man. Never was this more true than in the case of the General Electric Laboratory. Its achievements have been discussed with authority by Prof. Thompson and will be fully itemized by Dr. Chandler. They are the work of many men to whom they have brought deserved distinction. None the less, the laboratory as the entity and organization which has made this achievement possible is a projection of the personality of Willis R. Whitney, and in this sense its achievements are his achievements.

Whitney returned from Europe in 1896 with a Ph.D. from Leipzig. He had left home a good American and he came back a truer one. He had absorbed in Germany what were then advanced and difficult theories in chemistry and physics and to their application to the solution of chemical and industrial problems he now brought vision and a contagious inspiration. To him a problem was an opportunity and his reaction to it was as reflex and immediate as a knee jerk. I remember that he once told me after a pleasant dinner in Syracuse, when the conversation had reached the eternal verities, that he didn't want to go to heaven unless there were problems there.

Naturally, therefore, he began at once the brilliant experimental work which has added much to our knowledge of solubility, colloids and the corrosion of metals. His fundamental research demonstrated the effect of the positive and negative ions on the precipitation of colloids. He found that the corrosion of metals was an electrochemical process and he was perhaps the first to focus public attention upon the great economic wastes resulting from preventable corrosion.

Whitney is a pragmatic scientist, and the essential and innate practicability of his mental processes found early expression in the successful method which he developed in association with Dr. A. A. Noyes for the recovery of ether and alcohol from collodion, a process which not only assured the commercial position of the photographic film, but which also in its subconscious and later influence upon the mind of Mr. Eastman undoubtedly played its part in effecting that gentleman's reincarnation as the mysterious and benevolent Mr. Smith to whom the Massachusetts Institute of Technology owes its present superb equipment.

I happen to know, for I had the honor of making the bid, that prior to 1900 he refused a doubled salary and remained an instructor at Technology, because he "would rather teach than be President." At the time I thought it an extraordinary example of devoted self-denial, but since then I have seen what happens to our Presidents and I would, without self-adulation, take the same position myself, much as I hate teaching.

ACADEMIC LIFE

Dr. Whitney's relation to the Massachusetts Institute of Technology has been intimate and concurrent with his professional career. Immediately upon graduation, in 1890, he was appointed assistant instructor in sanitary chemistry in that institution. He had, we may assume, no strong directive impulse toward that branch of the science, but he demonstrated at once his characteristic ability to adapt himself to the job, and with it to identify himself. In 1892, by the slow process of academic preferment, he was promoted to instructor, but after serving for two years his desire for the advanced training and broader contacts with the scien-

tific world then offered by Germany caused him to enter the University of Leipzig. Upon his return to the Institute in 1892 he was appointed instructor in theoretical chemistry and proximate analysis. Fortunate indeed were those students whose schedule brought them under his influence. It would be interesting to know how many of them appreciated the quality and recognized the potentialities of their instructor.

He became, in 1901, assistant professor of theoretical chemistry, in 1904 non-resident professor of theoretical chemistry, and in 1908 non-resident professor of chemical research. More recently he has become a member of the Corporation of the Institute and he has served as chairman of its committee on the department of chemistry and chemical engineering, and is now active as chairman of the committee on the department of physics. It is a matter of general comment and satisfaction within the instructing staff that he has never lost interest in the school. Visiting committees of the Corporation too often do not visit. But Dr. Whitney came upon the job determined to know its every aspect. He spent days in the laboratories. He sat down by students; into them he injected his own enthusiasm. He studied the needs of the departments and he followed his studies by helpful suggestions and constructive criticism.

IDEAL CHARACTERISTICS

One very conspicuous element in Whitney's character is the sincerity of his indifference to monetary rewards. It is the more striking because of the clarity with which he visualizes the economic aspects of research results. He went to the General Electric Co., as I confidently believe, not for money, but because it offered an environment and opportunity for broader and more effective service. I am no less confident that he would return to Tech. tomorrow and readjust his expenditure within the narrow boundaries of a professor's salary if he felt that there he could do a better job.

I wonder how many of you have realized how closely in appearance Whitney resembles Lizst. One expects of him—and is not disappointed—the same fire and enthusiasm, a kindred brilliancy of performance, a similar exothermic quality. Whitney can talk to a man three minutes and inject into him enough enthusiasm to last three months. He can recognize genius and he is big enough to allow the man of genius to develop at his side. He has no wish and makes no effort to dominate. He scrupulously apportions credit where it belongs. Jealousy is alien to his nature. These are the characteristics of the ideal director of research, and it is because they are possessed in superlative measure by Willis R. Whitney that we are present here tonight.

HUMAN ELEMENTS

Willis R. Whitney is a great scientist, but he is not the scientist of fiction or of the stage. He is an intensely human individual. He is extremely fond of outdoor life and it keeps him sane and wholesome. He is a farmer, not a gentleman farmer but a dirt farmer who knows hog cholera and manure and what to do when his hens have the pip. He has hobbies and rides them. He can tell you more about arrowheads than an Algonquin Indian ever knew, and if necessary he can make them. He usually prefers to pick them up in Central Park or Long Acre Square, or at church. He can find them anywhere. He enjoys the lighter things of life and has even been known to sidestep a meeting

of the American Academy of Arts and Sciences, and go to a girl and music show instead. Biological subjects (and I am not now referring to those just mentioned in association with music) interest him keenly. He raises flies and kills them with X-rays to cure their cancer. Some day he may kill the cancer first. He is a serious student of heredity and knows exactly how much red hair is required to tint a large family unto the third and fourth generation. But do not let me convey the impression that Whitney approaches these vocational interests in the spirit of the dilettante. His knowledge of them is not broad and thin, it is both broad and deep. When he cultivates a subject, he does it intensively with all the energy in him. Better than all this, however, Whitney has a genius for friendship. He knows you but likes you.

With this interest in his fellowmen so dominant and characteristic, it is not surprising that Whitney should have proved an ideal teacher or that no later absorption has turned his thought from education. He inspires whole departments in the Massachusetts Institute of Technology; he is the prime mover of Albany Medical College, and as trustee of Union College at Schenectady has so tied his laboratory to the college that they constitute a joint educational institution.

In a very striking way and more nearly, as it seems to me, than any of his contemporaries, Whitney has the mental attitude and scientific breadth of an earlier generation in the scientific world, the ability to correlate and integrate observations and deductions in wide and different fields.

The Perkin Medal is the badge of knighthood in American chemistry. It has never been more worthily bestowed. Its latest recipient has inspired numberless young men; he has brought distinction to a great corporation and proved to financiers that research pays; he has brought new luster to American chemistry. The spirit of research has laid her hands upon him, and the spirit of youth as well.

Presentation Address

BY C. F. CHANDLER

It is my privilege and very pleasant duty as senior past-president of the Society of Chemical Industry, residing in this country, to present to Willis R. Whitney, S.B., Ph.D., the fourteenth impression of the Perkin Medal, in recognition of his most original and valuable work in applied chemistry.

Dr. Willis R. Whitney was born in Jamestown, N. Y., Aug. 22, 1868, and was the son of John and Agnes (Reynolds) Whitney. He was graduated from the Massachusetts Institute of Technology with the degree of S.B. in 1890, and in 1896 received the degree of Ph.D. from Leipzig.

RESEARCH LABORATORY OF THE GENERAL ELECTRIC CO.

His most notable achievement has been the creation and development of the Research Laboratory of the General Electric Co. at Schenectady. This laboratory, one of the earliest of its kind in this country, the embodiment of the application of science to industry, has gained a world-wide reputation by the quality of its work and the importance of its results. These results speak for themselves, but only those associated in the laboratory with Dr. Whitney can realize to what extent they are due to him personally, or how truly the story of the laboratory, from its inception with

a small staff to its present development with 275 people on its payroll, has been the story of his personal achievement. Its growth has followed naturally from the value of its accomplishment, but its accomplishment has been due primarily to him. His broad scientific knowledge, his ability as a chemist, his resourcefulness in experiment, his energy, enthusiasm and optimism, combined with a clear sense of proportionate values, laid the foundation for, and guided and inspired, all the work of the laboratory, while his democratic and magnetic personality created an *esprit de corps* in his staff which has been a powerful factor for success. This must be realized fully to appraise justly his personal achievements in considering the success of the laboratory.

These successes have often been recited specifically to prove the value of the application of organized research to industry. In electric lighting the first radical improvement in the carbon incandescent filament, since Edison first produced it, was due to Dr. Whitney's personal work. The "metallized" filament, or "Gem" lamp, which he developed and which embodied a new form of carbon, gave 25 per cent more light for the same wattage than the standard carbon filament lamp. Millions of these new lamps were sold in a single year. A little later the laboratory made a still greater contribution to electric lighting, by solving the problem of mechanically working tungsten and taught the world how to make the drawn wire which has given the tungsten lamp its universal application. The latest achievement of the laboratory in incandescent lighting is the gas-filled or half-watt lamp, which, in its larger sizes, has twice the efficiency of the vacuum lamp, and nearly equals the most efficient arcs. In arc lighting

the laboratory developed the magnetite electrode, and thereby produced the most successful arc lamp of today.

The laboratory has produced many new and useful forms of insulations and molded compounds, many new alloys for resistance units and other purposes, new processes, like "calorizing," for giving metals protective coatings; new articles of manufacture, like "sheath wire," with its core of resistance alloy, its mineral insulation and its metal sheath, adapted for heating devices; new materials, like "water japan" and "Genelite"; new electric-furnace products, like boron carbide, useful as a flux for casting copper, and titanium carbide for arc lamp electrodes; new laboratory tools, such as the Arsem vacuum furnace, the tungsten tube furnace and the Langmuir condensation vacuum pump; high-resistance units for lightning arresters, improved carbon and graphite and Metite brushes.

The development of wrought tungsten has been followed by several important applications worked out entirely in the laboratory. Tungsten contacts have practically replaced platinum in spark coils, magnetos and relays, and tungsten targets have replaced platinum in X-ray tubes.

As a result of a study of high vacuum, the laboratory devised means and methods for producing much higher vacua than before obtained, and the study of the phenomenon of electron discharge in high vacuum has produced a number of new types of vacuum tubes which have revolutionized more than one art. The Coolidge X-ray tube was the earliest result of this investigation and has practically displaced all other types of X-ray tubes. It has made possible many results not otherwise obtainable, as, for instance, the development of a truly portable X-ray outfit. Another result was the plotron,

the first real power tube suitable for radio transmission. The plotron practically created radio telephony and has revolutionized radio telegraphy. Other types of these tubes resulting from this investigation are the dynatron, magnetron, pliodynatron, etc. The contributions of the laboratory to pure science have been numerous, varied and important, as is indicated by the titles taken from the list of laboratory publications:

Factors Affecting Relations Between Photo-electric Current and Illumination.

Structure of the Atom.

Theory and Use of the Molecular Gage.

Theory of Unimolecular Reaction Velocities.

Absorption and Scattering of X-Rays.

New Method of X-Ray Chemical Analysis.

New Method of X-Ray Crystal Analysis.

Roentgen-Ray Spectra.

High-Frequency Spectrum of Tungsten.

Arrangement of Electrons in Atoms and Molecules.

Chemical Reactions at Low Pressures.

Constitution and Fundamental Properties of Solids and Liquids.

Dissociation of Hydrogen Into Atoms.

Effect of Space Charge and Residual Gases on Thermionic Currents in High Vacuum.

Evaporation, Condensation and Reflection of Gas Molecules.

Fundamental Phenomena in Electron Tubes Having Tungsten Cathodes.

Isomorphism, Isosterism and Covalence.

Mechanism of the Surface Phenomena of Flotation.

Octet Theory of Valence and Its Applications With Special Reference to the Organic Nitrogen Compounds.

Properties of the Electron as Derived From the Chemical Properties of the Elements.

Structure of the Helium Atom.

The Structure of the Hydrogen Molecule and the Hydrogen Ion.

Dr. Whitney is a trustee of the Albany Medical College and of Union College, and a member of the Cor-

W. R. WHITNEY

poration of Massachusetts Institute of Technology. He is a member of the U. S. Naval Consulting Board, National Research Council, American Chemical Society (president in 1910), American Electrochemical Society (president in 1911), American Institute of Mining and Metallurgical Engineers, American Institute of Electrical Engineers, American Association for the Advancement of Science, American Academy of Arts and Sciences, American Physical Society and British Institute of Metals. He received the Willard Gibbs Medal in 1916 and the Chandler Medal in 1920.

PUBLICATIONS

Dr. Whitney's translation of Le Blanc's textbook of electrochemistry is well known. Among the papers which he has personally published, are the following:

1. The Rate of Solution of Solid Substances in Their Own Solutions (with A. A. Noyes). *J. Am. Chem. Soc.*, vol. 19, pp. 930-34 ('97).
2. The Nature of the Change From Violet to Green in Solutions of Chromium Salts. *J. Am. Chem. Soc.*, vol. 21, pp. 1075-84 ('99).
3. The Precipitation of Colloids by Electrolytes (with J. E. Ober). *J. Am. Chem. Soc.*, vol. 23, pp. 842-63 ('01).
4. An Investigation of Ammonio-Silver Compounds in Solution (with A. C. Melcher). *J. Am. Chem. Soc.*, vol. 25, pp. 69-83 ('03).
5. The Corrosion of Iron. *J. Am. Chem. Soc.*, vol. 25, pp. 394-406 ('03).
6. Electrolysis of Water. *J. Phys. Chem.*, vol. 7, pp. 190-93 ('03).
7. The Migration of Colloids (with J. C. Blake). *J. Am. Chem. Soc.*, vol. 26, pp. 1339-87 ('04).
8. Colloids. *Trans.*, Am. Electrochem. Soc., vol. 7, pp. 225-36 ('05).
9. Arcs. *Trans.*, Am. Electrochem. Soc., vol. 7, pp. 291-9 ('05).
10. Suspensions in Dilute Alkaline Solutions (with Alonzo Straw). *J. Am. Chem. Soc.*, vol. 29, pp. 325-29 ('07).
11. Organization of Industrial Research. *J. Am. Chem. Soc.*, vol. 32, pp. 71-8 ('10).
12. Some Chemistry of Light. *J. Am. Chem. Soc.*, vol. 32, pp. 147-59 ('10); Presidential Address, American Chemical Society, Dec. 29, 1909.
13. Alloys. Amer. Foundrymen's Assoc., 1910.
14. Chemistry of Luminous Sources. Johns Hopkins University, 1910; Lectures on Illuminating Engineering, Vol. 2.
15. Research as a Financial Asset. *Electrical World*, vol. 57, p. 828 ('11); *J. Ind. Eng. Chem.*, vol. 3, pp. 429-33 ('11); *Science*, vol. 33, pp. 673-81 ('11); Congress of Technology.
16. Mental Catalysis. *MET. & CHEM. ENG.*, vol. 9, pp. 179-82 (April, 1911). Opening Chemists' Building, New York.
17. Theory of the Mercury Arc Rectifier. *G. E. Rev.*, vol. 14, pp. 619-21 ('11).
18. Carbon Brushes. *J. Ind. Eng. Chem.*, vol. 4, pp. 242-46 ('12); *J. Frank. Inst.*, vol. 176, pp. 239-50 ('12).
19. Electrical Conduction. *Trans.*, Am. Electrochem. Soc., vol. 21, pp. 19-26 ('12); Presidential Address, Am. Electrochemical Society, April 19, 1912.

21. Vacua. *Trans.*, A. I. E. E., vol. 31, (1), pp. 1207-16 ('12); Publications of the Research Laboratory, vol. 1.
22. Phenomena of Catalysis. *Science Conspectus*, vol. 3, pp. 84-8 ('13).
23. Light. *G. E. Rev.*, vol. 17, pp. 171-4 ('14).
24. Relation of Research to the Progress of Manufacturing Industries. *Annals*, Amer. Acad. Polit. and Social Sci. No. 870 ('15).
25. Research. *G. E. Rev.*, vol. 18, pp. 1012-14 ('15).
26. The Corporation. *Trans.*, Am. Electrochem. Soc., vol. 29, pp. 36-8 ('16).
27. Preparedness. *J. Ind. Eng. Chem.*, vol. 8, p. 298 ('16).
28. Water Power and Defense. A. I. E. E. (Advance Paper) ('16).
29. Two untitled papers. One was published in *American Defense*.
30. The Call for Research. *National Defense Digest*, 1916.
31. Research and the Newlands Bill. *MET. & CHEM. ENG.*, vol. 14, pp. 565-66 ('16).
32. Research as a National Duty. *Science*, vol. 43, pp. 629-37 ('16); *J. Ind. Eng. Chem.*, vol. 8, p. 533 ('16).
33. Incidents of Applied Research. *J. Ind. Eng. Chem.*, vol. 8, pp. 560-4 ('16); Willard Gibbs Medal Address.
34. Research Organization. *G. E. Rev.*, vol. 19, pp. 572-78 ('16).
35. The Newlands Bill and National Research. *MET. & CHEM. ENG.*, vol. 14, pp. 621-3 ('16).
36. Practical Significance of Pure Research. Paper for American Mining Congress, Chicago, November, 1916.
37. The Undeveloped Powers of the South. *Manufacturers' Record*, vol. 70, pp. 58-9 (September, 1916).
38. The Great Need of Promoting Research in America. *Electrical World*, vol. 68, pp. 12-14 (Jan. 6, 1917).
39. Research. *G. E. Rev.*, vol. 20, pp. 114-20 (February, 1917); Address at Alumni Dinner of Mass. Institute of Technology, Jan. 6, 1917.
40. National Need of Scientific Research. *Yale Review*, April, 1917.
41. American Engineering Research. *Proc.*, A. I. E. E., vol. 37, p. 115 ('18).
42. Patent Renewal Fees, *J. Ind. Eng. Chem.*, vol. 11, p. 936 ('19).
43. What is Needed to Develop Good Research Workers? *Electrical World*, vol. 75, p. 151 ('20).
44. The Littlest Things in Chemistry. *J. Ind. Eng. Chem.*, vol. 12, p. 599 ('20); Chandler Medal Address.

CONFERRING THE MEDAL

Willis R. Whitney, Bachelor of Science and Doctor of Philosophy:

It gives me the greatest pleasure, as the representative of the Affiliated Chemical and Electrochemical Societies of America, to place in your hands this beautiful Perkin Medal, as a token of the appreciation and affection of your fellow chemists.

The Biggest Things in Chemistry

BY W. R. WHITNEY

If I were to try to justify my receiving the Perkin Medal I think I would begin by assuming that now good intentions are being rewarded. As the aim of the award is to promote or stimulate research, I must find the ways by which I can most directly do so, and so I ought to say something about the biggest things in chemistry. No matter how irrelevant some of my remarks may seem, I hope you will believe that they are aimed with that high intent. While it is a great honor, it is also a wonderful opportunity to write something which may be read by 15,000 or more American chemists.

In America patents are granted to individuals for their new disclosures. Such patents are not granted to organizations, to companies, nor even to laboratories. This is really an antique limitation, for discoveries are often the result of combined efforts. And so I look at the Perkin Medal, in my case, as an award directed to me, but belonging to the Research Laboratory to which I belong, it having not yet become customary to award such medals to laboratories. In any case, I heartily thank the various men and organizations which made this medal possible, and the committee of award who have chosen that my name shall stand on that honor list headed by Perkin.

I am not going to tell of the specific researches in which I may have co-operated, nor of the good fellows who have carried them out in our laboratory, though

I should like to do so. One reason is that this is, to a considerable extent, being done all the time, through our laboratory system. We have always followed the plan of individual publication as completely as seemed desirable from the scientific point of view and as rapidly as consistent with fair commercial conditions. Moreover, I, being almost the only man in our laboratory who does not often personally carry through separate researches, have already summarized the work of others until it is overdone.

What I have to say oscillates about a central point. This point I see so well that I am surprised that every one does not see it too, and make more use of it. I am also at a loss to know why so many men go through college keeping their eyes mainly on a ball of some kind or other when the world is so full of greater interest. Perkin's life contains all the data which we need in analyzing scientific research, and shows at once what I will repeat throughout this paper—that our great advances are usually made by men who are trained in their particular line of work and are working diligently just beyond the boundaries of the known.

Perkin was a student of chemistry in one of the best college laboratories in England, under a great teacher (Hofmann), who was so imbued with the chemical research spirit that he tried to keep Perkin from stopping to develop technically his discovery of mauve. He actually left such an impression on this young man's mind that after years of commercial success Perkin returned to pure scientific research and enjoyed it for the rest of his life.

The essentials appear to be: First, the teacher, enthusiastic pioneer, hunting and fishing along that ever-expanding outer rim of knowledge; then the laboratory and equipment, supported by some far-sighted government, individual or organization. And then the school-boy with shining morning face. Don't say it can't be done, and that Perkins, Faradays and Pasteurs are born, not made, for the process is entirely standardized. We in our schools have not realized the proper sequence, because we have used so much of our energy in bringing large numbers of men part of the way only.

On receiving the first Perkin Medal at the time of the Jubilee Celebration Sir William Perkin said that he had all his life insisted on the importance of research and that this medal would accomplish a valuable result if it helped to encourage and stimulate activity in that direction. He then proceeded to tell the interesting story of his own discoveries. Such a story is the strongest force he could have used to support his wish to promote research, and it is true that, although it would have been more agreeable to him if some one else could have told the story, everyone who heard it and the countless chemists who live to read it are glad no one else told it.

EARLY INTEREST IN CHEMISTRY

No greater satisfaction in connection with my own life's work could come to me than to contribute to the encouragement and stimulation of research. If I can help it to an appreciable extent by telling any unpublished portions of my own story I will willingly disregard for a few moments a natural reluctance to talk about myself.

I learned that Prof. Perkin became a chemist through the influence of an Englishman named Hall, with whom he came into contact when under fifteen years of age, and, moreover, an event which increased his desire to become a chemist was seeing an experiment showing

the growth of certain crystals. I have the honor to have started as a chemist in this identical manner, and I will tell a little more about it, because I have always wished I had some way of expressing my gratitude to my particular Mr. Hall.

When I was about fifteen years old an English mill owner and one of the leading citizens of my home town, William C. J. Hall, assisted in establishing a Young Men's Christian Association. He had also long been interested in the microscope and was a scientist such as we seldom find among business men today. He formed a free evening class for about half a dozen boys—all that could work together around the rotating table on which he placed his immense microscope. This was so arranged that specimen, instrument and illuminating system did not have to be disturbed as they passed from one boy to another for observation. He did not merely show his specimens, of which he had thousands, but taught us how to prepare them in all the various ways now more or less common. They were all wonderful to me, and still are.

My mother gave me some money which, combined with that of one of the other boys, purchased a small microtome, and my father gave me \$75 for a microscope. Under Mr. Hall's guidance I bought the instrument, with the understanding that whenever I wanted a better one the old one would be taken back at the original price. I later procured one for \$250 which, throughout thirty-five years, I have used almost daily. One of the first experiments I tried with the microscope was to precipitate metallic silver from silver nitrate solution onto a speck of copper filings. Anyone who has watched these beautiful crystals grow knows that they are surpassingly wonderful. They constituted my first chemistry. It was those little bottles of salts and bugs in alcohol that led someone to call me a chemist, and it apparently determined my future work.

It does not seem now as though anyone else ever enjoyed a tenth of the pleasures my old microscope introduced to me. I find them inseparably interwoven with about everything I know. Even the barren North Pole reminds me of Andrée and Amundsen and microscopic algæ which drifted across the polar circle from the Lena delta. The equally barren Sahara reminds me of Darwin and De Vries and the diatoms which were carried by the wind from central Africa and fell on the deck of the Beagle, hundreds of miles away.

CONCENTRATING ON THE IDEAL

In trying to put the truthful personal and human element into these notes, as previous Perkin medalists have done for the help of would-be research men, I find I cannot lay valid claim to the insurmountable difficulties nor to especially commendable early struggles which have helped so many others. Perhaps even this admission, however, may have its place for the encouragement of some research man. I was early taught that a dollar a day was a fair wage and that frequently was unearned, and I quit worrying about pay so long ago that the date is not important. I once asked the president of a large technical school for a salary increase of \$75 a year and was shown that it could not be done. Perhaps that wise president convinced me that financial rewards are not the main thing. At any rate I believe it.

In mapping milestones not mentioned before I want to express my indebtedness to Prof. A. A. Noyes, who showed me some of the interesting things in the science of chemistry. He let me work with him on some

physicochemical researches, and this work was responsible for my later spending two years with Ostwald in Leipzig and a summer with Friedel in Paris. Work with these men gave me a feeling of surety in chemistry that no mere talk could ever have done. I ought to say that one of our first joint researches, so far as publication was concerned, had the peculiar effect of freeing me forever from the wiles of college football, and if that is a defect make the most of it! Dr. Noyes and I conceived an idea on sodium aluminate solutions on the morning of the day of a Princeton-Harvard game (as I recall it) that we had planned to attend. It looked as though a few days' work on freezing point determinations and electrical conductivities would answer the question. We could not wait, so we gave up the game and stayed in the laboratory. Our experiments were successful. I think that this was the last game I have ever cared about seeing. I mention this as a warning, because this immunity might attack anyone. I find that I still complainingly wonder at the present position of football in American education.

THE BIGGER THINGS

I would prefer now to talk about the biggest things in chemistry, not so that I may be facetious, nor yet to form a companion piece to a talk on the littlest things. Far from it. In fact, so far from it that after having some of my thoughts in preliminary notes for years, with a conviction that they ought to be expressed, I have always deferred it. I feared that I was not just the man to say it.

We are all interested in the detailed and specific advances which constitute our science. We know that it is from these little things that the largest ones grow. We see a certain similarity between the history of Prof. Perkin's mauve, with its subsequent enormous development of the dye, medicine and explosive industries, and the development of the living acorn into the spreading oak tree. But we should sometimes look at the forests from the plains, without obstructions. And we want to know our chemistry, too, in its relation to the general landscape. Some kind of an inner man advises us not to think exclusively of the littlest things, the parts of some whole, but sometimes to give constructive thought to the ultimate objects, to our aims at large, our chief pretensions, our real ambitions, our main direction of motion. Are these consistent with or independent of our temporary and apparently vacillating movements?

I know from experiment (as we usually say) that no two chemists would agree at first as to what constitute the most important things of chemistry. I have found, however, that if we say that the "possibilities" are the biggest things, then today there is some agreement among experts.

TESTED LAWS

Chemistry is one of those branches of human knowledge which has built itself upon methods and instruments by which truth can presumably be determined. It has survived and grown because all its precepts and principles can be retested at any time and anywhere. So long as it remained the mysterious alchemy by which a few devotees, by devious and dubious means, presumed to change baser metals into gold it did not flourish, but when it dealt with the fact that 56 g. of fine iron, when heated with 32 g. of flowers of sulphur, generated extra heat and gave exactly 88 g. of an entirely new substance, then additional steps could

be taken by anyone. Scientific research in chemistry, since the birth of the balance and the thermometer, has been a steady growth of test and observation. It has disclosed a finite number of elementary reagents composing an infinite universe, and it is devoted to their inter-reaction for the benefit of mankind. The rate of this advance in chemistry is in our day almost incredibly great.

THE HISTORY PATH

Mark Twain's little history game has given me a view of our rate of development, and particularly of modern as compared with ancient affairs, that I want to pass along to you. Possibly some of you have thought of the rate of mental development, of material development and of power developments as involving only a fairly uniform change through all time. This is not so at all. But to shorten this story: I started from a certain point in the woods with a measuring tape and marking tools and laid out a winding path 1,000 ft. long. I cut smooth marking places on all trees along the way and on some large rocks. I appropriated 1 ft. length of this path for each year's history since William the Conqueror (the year 1000), and spent the rest of my time properly locating prominent events along the path, down to 1,920 ft.

I was impressed by the 45-ft. length of Queen Elizabeth's reign, near the middle of the way, and such a short distance from Columbus and the discovery of America. Stockings and pins and sugar (except as medicine) came into the path about there. But of interest to us particularly is that all the great chemists began to arrive together near the 1,850-ft. point. This seemed very recent. It meant that most of the superstitions about matter began to disappear only about 250 ft. back, so to speak. You all know the story, but for 75 or 80 per cent of my measured path, and for the interminable portion representing all time prior to 1000 A.D. (which I let wind without construction or destruction back the mile or more which might still have been historically illustrated), there had been no need for more than four supposed elements, earth, air, fire and water. It was not the old facts but the dimensions which impressed me. While a foot is ample space in which to erect monuments to everything we know about any year chosen in the fifteenth century, and a single tree could be signpost for all the cards on events for any century a little earlier, there was great lack of space for descriptive matter beyond the 1,800-ft. point.

All down the line, to within a stone's throw of the end, individual man-power had been the important energy, and then as power it almost disappeared. Within 200 ft. of the end, which stood for the present day, steam had been put to use, and there came in turn the myriads of machines which multiplied a thousand-fold the previous constant and limited muscular power of man. No one can accurately determine the added spread of effort due to this substitution of coal for human strength, and then of machines, one for another.

Within 30 ft. of the end of the path a score of new chemistries had grown into activity, and every single one seems more promising than the original stem: physical, colloidal, subatomic, radio, metabolic, biologic, enzymic, piezo, therapeutic—all growing infants. Thus the time seems almost near when, to quote Carnegie, "the mind, like the body, can be moved from the shade into the sunshine."

This interesting game of Mark Twain's actually

chokes itself off mechanically when one tries to post modern chemical work at one foot per year. New facts now take about that space when posted edgewise in abstract journals, a dozen items per page. What this game, applied to chemistry, had done for me is to show me the almost inconceivably great strides in countless lines which constitute our modern chemistry, and it leaves me with the feeling that no one in the world has ever had such possibilities open to him as the present-day student of chemistry.

CREATIVE CHEMISTS

Perkin was a well-prepared research chemist when he made his discoveries. He was just the kind of man of which we produce too few. Only a very small number of our students get so far in the science as he went under Prof. Hofmann, and nowadays, in order to go so far, one must go much farther, for, as Wendell Phillips said, "to be as good as our fathers were, we must be a good deal better." The process Perkin followed is the same one which has led to most of our discoveries. It is the encouragement of natural inquisitiveness under the best conditions. It is using the newest knowledge and best tools in exacting pieces of work. No short-cut and easy process would have produced dyes from tar. Such efforts could not even find a way to make tar acceptable for road material.

One of the biggest things in chemistry for us today is to learn how to bring about the productive teaching of chemistry. The desirable qualities are illustrated by the life of Wöhler, who prepared the first organic compound when the consensus of opinion (and infinite argument) favored the theory that organic compounds were only producible through a mysterious vital force. Pasteur's work is another case of a trained research chemist, and every American should learn his ways. What such explorers seek are not imaginary points on a drifting field of perpetual ice in an uninhabitable world, but something which may possibly help every individual who lives after them.

We might have similar results developing in chemistry today, but they call for the good teachers and the highly trained observer, with well-backed faith. These two, high training and faith, are an uncommon pair with us. They seldom grow within the same Yankee.

EXPANSION OF INORGANIC DEVELOPMENT WORK

I need not repeat what is known about the many disclosures of inorganic chemistry. How, within the past few years, chemical science has at least doubled the number of available metals, and so raised to the n th power the possible alloys. All these new metals are generally coming into use, as you know.

I am often reminded of metallic calcium in this connection, because it is really still being born, but the process is the old one. It was produced by high-grade electrochemical research, and the discoverer in describing the process said: "We do not know now of any use for this new metal, but when its properties and production are understood it will probably find its place."

It is almost useless to think otherwise. Here is a chemical element the compounds of which are as numerous and whose ores are as rich as those of any element known. The isolation of the metal is not so simple as in the case of zinc, copper, iron or tin, and its properties are different, but, as usual, it is differing properties which determine the new use. It is worth telling in passing that during the war we made this

metallic calcium and found two widely different uses for it. One was as a suitable generator of hydrogen to maintain very high pressure of this gas inside certain deep-sea sound-detecting devices, where the sea water itself was the other reagent. The reaction was slow and well suited for this work. The other use is as a continuously reacting purifier for argon in the tungar rectifier. This latter is now the basis of a considerable manufacturing business. It is interesting, from the chemical research standpoint, because it consists of a bulb made of a special new glass, a tungsten wire spiral, an artificial graphite electrode, a little argon gas and some metallic calcium. Within the spread of my brief experience there was a time when any part of this combination would have been an impossibility from lack of every one of these chemical materials. And so I note such researches as Prof. Lehner's on selenium oxychloride, and I say to myself, "Watch it grow." To add such a liquid to our little category will prove an ever growing utility.

We ask ourselves, Can there be greater fields of new organic chemical research than that which met Perkin as a student? Is not tar the last big raw material? The answer is simple. New fields are greater in number because the territory of chemical knowledge is so greatly broadened and the new tools are so numerous. The results will depend solely on mentality—not tar. Is it not within reason that another as great a field as dyestuffs will be developed directly from carbon itself, for example? The entering gates to organic chemistry, reached by the shortest road, were apparently opened when calcium carbide was first made. Thus, starting with two of our most abundant mineral products, coal and limestone, and adding water alone, we are supplied with the endothermic gas, acetylene. From this point almost anything organic seems possible. When we realize that the manufacture of acetone, alcohol, etc., has been thus made possible from these inorganic raw materials we might as well expect, by the same road, useful food as certainly as medicaments.

I am repeatedly pointing to need in our country for the highest class of chemical preparation. It is not enough to talk of the importance of fuel, of the conservation of coal, of the possible use of benzene or alcohol in our motors. Such have already become problems, and we have a hundred thousand engineers in the country capable of solving them. Some of these men have already carried out the manufacture and use of hexahydrabenzene in motors, for example, but the chemistry itself, as a science, though still infinitely promising, is relatively neglected.

EXPERIMENTS IN AGRICULTURE

Possibly one of the biggest things in chemistry lies in agriculture, but it would be futile for me to treat of its research by the modern truthful but standardized method. It is admitted that we need more and better fertilizers. We now use nearly \$200,000,000 worth annually. It is true that we have recently spent many million dollars on nitrate plants. We also think we need half a million tons of potash annually, and of this we can see how to produce locally only about 10 per cent. We want synthetic ammonia and we can get it, because during the war we were forced to adopt production methods derived from foreign chemical research.

I do not need to go farther with agriculture in order to prove that I am not a real farmer, but I insist on doing so because I want to make clear the thought that possibly our troubles in general with Nature are some-

times due to our personal limitations, not to the limitations of Nature.

It looks to me as though possibly man had developed most of the cultivated fruits of the field along the line of maximum human exertion and immunized them to everything else. I draw this hasty conclusion from a single experiment of my own. Last year I procured some special high-grade seed corn and treated portions of it in widely different ways. In one case the kernels were planted, properly spaced, through holes in large sheets of paper placed on new ground which had had its grass killed by a year's covering with gravel, which was then removed. The paper was to discourage the weeds and make hoeing unnecessary. Other hills were planted without the paper, and still others in which the soil was taken up, softened and replaced. None of these new-type gardens was disturbed during the summer. Less radical experiments, including nothing at all but muscular effort, were tried on other hills in an old type garden.

Knowing how corn had been produced through thousands of years of applied work, the results could have been foreseen. All that grown on new soil, protected by paper from weeds and from evaporating winds, took the whole summer to grow about a foot high. It looked very mature, but didn't bother to produce any ears. That which had been about buried in modern artificial fertilizer, and well hoed, pulled through somehow, and that which had been manured and most energetically hoed did the best and gave a normal corn crop.

The growing of corn and grain is an older process than making wire nails and cannot be so easily improved. It has developed with no fair regard to human labor, and will take more novelty of effort to change it than was employed in freeing manual labor from nail, screw and bolt making, or from the production of artificial indigo or synthetic camphor.

When one reads of the experiments of Loeb on the rate of growth of bryophyllum shoots as influenced by various schemes of cutting leaf from stem, etc., one can hardly doubt that new truth, learned for itself alone, in some such way, may at least rearrange some parts of future agricultural research. Anyone who has annually tried to kill a burdock by any means short of complete eradication, or who has watched the persistency with which a lot of wild chicory will grow to maturity in the almost imaginary crack between a reinforced concrete road bed and the adjoining separate curbstone, will appreciate the thought that some time, somehow, man may successfully direct his researches toward the growth of useful vegetation with reduced, not increased, human labor.

MEDICAL RESEARCH

Many biggest things in chemistry are coming from chemical research in the field of life and health. When I recall the Rockefeller Institute for Medical Research and think of the international character of its men and work I incline to the belief that through such researches in chemistry and allied sciences the countries of our world may be more certainly finally allied than by the system of countless peaceful words coupled with increasing armaments. There I have seen Carrel, French scientist of the purest type, keeping chicken tissues growing on microscope slides for nearly a decade in order that he may carry out those quantitative experiments which lead to exact medical science. In such an institution a class of refined and exhaustive research

work can be done whose results stand as foundation stones on which doctors and surgeons of all lands may build at once. The diplomacy of such institutions leaves no room for international spies. The results, as soon as verified, are published to all quarters of the globe. Jacques Loeb, studying the amphoteric properties of gelatine or the temperature coefficient of the life-reactions of fruit flies, is putting permanent points of observation on the graph of human knowledge where all may see, confirm and use them. The little Japanese Noguchi, a most attractive enthusiast and a co-worker of Dr. Flexner's for nearly twenty years, is now all wrapped up in yellow fever work. He has isolated the germ and prepared the preventive vaccine and the immunizing sera. Thus he adds some of the finishing touches to that story of a fight which has been under way since 1900, when Dr. Lazear knowingly risked and lost his life by letting a certain mosquito bite him.

WONDERS OF THE BRAIN

If we think of the brain as the workshop of the mind, and then look back over the history of the growth of brains, we find that this workshop first appeared as a relatively *very* small portion of the mass of the early animals. All the prodigious vertebrates of the mesozoic period had exceedingly small brains in proportion to their bodies. The brain size in comparison to the size of the animal has always been on the increase. In man and his forerunners this is also well known. But it is significant that even with man there is no continuing brain growth when he is kept from doing or thinking something new. The Egyptian fellaheen, who were kept at unchanging labor for many centuries, possessed the same size brain cavity at the end as at the beginning of that period. But the diameters of the brain cavities of the early man-forms after the chimpanzee (the Trinil, Piltdown and Neanderthal men) stand to man as at present in about the relation of the numbers 12, 13, 14 and 15.

And yet, in this most modern workshop, the energy which is consumed is so small, when compared to the work done by other organs of the body, that it cannot be measured as energy at all. It is easy to measure the work done by the little finger and express it in calories consumed from the food eaten. The most extensive mental exercise is much more economical of energy. In other words, we have not yet taxed the mind's workshop from the energy or work point of view. All this means that, following the direction of natural development, there need be no lack of that brain power or mentality which is needed to handle all that we may wish to know and think.

MENTALITY

The biggest thing of all in research is the mental effect, the projecting of a beam of light into the infinite and the growth of man's appreciation. I can scarcely touch the many connections here. But in delicacy and sensitiveness the mind far transcends the wireless receivers which yet read, half around the world, a message sent by a few watts of energy. And I need say nothing about its possibilities as a power producer or controller. In co-operative work minds multiply, instead of adding together, and growth of mind depends on the experiments or the reactions with things. Whether mind is polarized energy, or merely a long habit, may still be in doubt, but there can be little doubt as to what expands it.

Not very long ago it was safer to conceal new truths

than to disclose them. If a man wished to die by some horribly ingenious method he had but to discover something like the rotundity or mobility of the earth and insist on it. For advocating justification by faith alone he would be burned alive. Dabbling with intangible matters which led only to disputation was gradually displaced by increased attention to immediate surroundings.

Is it too much to say that through research into materials the main advances in physical and mental welfare take place? Where do we meet contradiction if we say that, except for research or experimental study of matter, we stand still or mill about in circles filled with superstitions? Particular attributes of the human mind may well have reached higher altitudes in some previous age, as is usually claimed. In specific lines of human undertaking we can but accept this as true. We have no Homer among our poets, no Cellini nor Angelo nor Da Vinci among our artists. Plato and Aristotle and many others ages ago equaled our present-day logicians. Such are the nuggets of truth which the seeker for values in history is apt to dig up. As architects or sculptors or hewers of stone we may be retrogressing, and in any selected development we may have passed zeniths, but all the time the knowledge of the universe and of each atom of it, from the tiny flower of the crannied wall to the sun which brings it forth and the stars which so immensely exceed this, has been rapidly increasing. The only perpetual motion is the growth of truth. Possibly faith, hope and love are not at a maximum in our age, but they may be, and through all ages there seems to run Tennyson's one "increasing purpose." Only one sure line of continuing increments can be traced. It is not the line of the search for waters of eternal youth. It is not the series of philosopher-stone experiments, though a few of them contributed to the steady growth of our horizon. It is not the line of ascetism, stoicism, religious tolerance or intolerance of any form, nor yet the political systems of the widest variety. They are now useless except as they added to the accumulating mass of truth. Appreciation of environment has always increased.

RELIGION

The natural desire for religious truth has been responsible for most colleges and universities. They served first to encourage learning and prepare religious teachers, but only recently has it become the recognized duty of universities to seek truth by investigation of material things. Goldwin Smith wrote of Oxford in the early days that, "For the real university students the dominant study was that of the school of philosophy, logical and philosophical, with its strange jargon; an immense attempt to extract knowledge from consciousness by syllogistic reasoning instead of gathering it from observation, experience, and research, mocking by its barrenness of fruit the faith of the enthusiastic student. The great instrument of high education was disputation often repeated, and conducted with the most elaborate forms in the tournament of the schools, which might beget readiness of wit and promptness of elocution, but could hardly beget habits of calm investigation or paramount love of truth."

The uptrending curve of recognized facts might be called Nature's appreciation curve, or the growth of mind. While cattle eat, drink and die with no more appreciative attitude toward their surroundings than shown in previous ages, mankind has accumulated, by

experiment, everything that distinguishes him. But certainly the end of this growth is far away and still out of sight. When men can talk so glibly about their closeness to a Creator and yet uniformly show, by destructive warfare, their extreme remoteness, surely the great undertaking, whatever it means, is not nearly complete. We have much to learn.

May it not be possible that the human urge for new truth, the world trend for clearness of vision in material things, will be justified? Can there be a better way of appreciating the wonders of creation than by looking into them, uncovering, understanding and appreciating them?

I should identify all search for scientific truth with the highest religious aim, no matter what the cult. I would point out here that our inactivity and inappreciation in the presence of infinite, undeveloped truth is the most inexcusable type of error and unfaithfulness. It is intense faithlessness, no matter what conception of a Creator we adopt.

There is no better (perhaps no other) way of going forward in the new paths which instinctively attract us than by using new material knowledge. Is it not possible that words of affection, of sympathy and promise of all kinds, helpful, heartfelt and beautiful as they may be, are only the paper money of our transactions, and that behind them there should be gold of service in which to pay the promises?

I do not look at this as crass materialism. We all know that the mere chemical reactions of the brain are not the whole story. A measuring machine repeating automatically all the motions of the scientist would not interest us at all. Appreciation of the infinite is not mechanical, but truth is necessary for appreciation. John Burroughs has said: "Every day is a Sabbath day to me. All pure water is Holy Water, and *this* earth is a celestial abode. It has not entered into the mind of any man to see and feel the wonders and mysteries and the heavenly character of this world." Yet most of what even John Burroughs sees and appreciates is outside of the infinitely beautiful and orderly realms of modern chemistry. When we are first old enough to ask ourselves questions we are so mature that we seem already surrounded by an infinitely complex and interesting environment. A persistent and age-old instinct makes us want to wander

"Into regions yet untrod
And read what is still unread
In the manuscripts of God."

And it has developed that in no other way may we hope to understand and appreciate. Chemists should naturally be the first and greatest appreciators. Research is appreciation.

Efficiency of Electroplating Greatly Increased

Much interest has been aroused by the account given at a joint meeting of the Faraday Society and the Institute of Metals held in Sheffield of a discovery made in the university of that city which will increase the output of electroplating factories by 100 per cent. Frank Mason, the inventor, who is lecturer in electrometallurgy and electrochemistry in the university, discovered by experiment that by a change in the chemical composition of the electrolyte the maximum current of the bath could be increased by over 100 per cent and the process of electroplating performed in less than half the time taken by the existing method.—*The Engineer*, Nov. 26, 1920.

Swedish Electric Pig Iron Furnace

Brief Description of the Constructional Details, Methods of Starting and Operation—Gray Iron, Low in Sulphur, May Be Had by High Power Input—Operating Figures for Long Campaign in 1920—Estimate of Cost

BY JONAS HERLENIUS

Secretary-Treasurer Hamilton & Hansell, Inc.

FOR various reasons the question of electric iron ore reduction has lately been of vital interest, not only in this country but throughout the world. The increased price of coke and consequently pig iron, the higher cost of transportation and the present ample development of cheap hydro-electric power in vast territories where suitable ores and charcoal are available for the production of a higher grade of pig iron, are probably the main reasons why this question has been brought into the limelight. Another fact, which may also have an important bearing on the subject, is that a certain type of furnace for this purpose has been successfully used in Sweden, although very little information regarding operating results and performances is available to anyone desiring to make a study of the situation. It is the object of this article to describe the Swedish electric pig iron furnace and to summarize briefly some of the results from its use as a commercial unit for iron ore reduction.

DEVELOPMENT

In 1909 the first Swedish electric pig iron furnace was installed in Domnarvet, Sweden. It was in operation for about three months, but afterward was shut down for a long period. On the basis of the results obtained, however, a special trial plant was built in 1910 at Trollhättan, Sweden, by "Jernkontoret" (the Swedish Iron and Steel Institute), on a government appropriation in order to develop an electric-furnace type that would satisfactorily replace the ordinary charcoal blast furnace. The trials were conducted with skill and accuracy by expert engineers for nearly two years and the results obtained proved to be very satisfactory, both from a practical and economical standpoint. Several of these furnaces have since been installed in various steel plants in Sweden, so that at the present time a total of twelve units are in operation in that country, ranging in size from 2,200 to 8,000 kva. transformer capacity. In addition, there are also similar furnaces in operation or contracted for in Norway, Italy, Japan and Brazil.

DESCRIPTION OF FURNACE

The furnaces are installed in buildings of brick, concrete or steel construction containing the entire furnace and its surrounding pig beds and provided with spacious charging floors. The furnace proper consists of a wide melting chamber or crucible, above which is a shaft with a bell-charging apparatus at the top. Fig. 1 is a section of a typical modern furnace; the dimensions are special for each installation and have to be calculated for the capacity, the kind of ore, the charcoal or coke available and the grade of pig iron to be produced. The shaft is thus designed in accordance with the general practice for common blast furnaces, except

for a recent tendency to widen out the lower section, making the diameter of the shaft at its junction with the crucible even larger than at the bosh.

The entire brickwork and shell plate of the shaft are suspended independently of the crucible. A steel ring is attached to the shell plate and rests on brackets and cross-girders supported by three or four columns, either a part of the furnace building or preferably independent of it. The bottom of the shaft is an iron ring, which makes a flexible joint with a corresponding watercooled ring serving as a skewback for the bricks in the crucible roof. The shell has an extension of from 6 to 9 ft. above the stockline and carries the charging bell. In this extension openings are made for the gas outlets.

The crucible is cylindrical and is contained in a mild steel shell resting on beams supported by a concrete foundation. The electrodes are inserted through the thin brick roof at an angle of about 65 deg. to the horizontal.

The entire shaft is lined with firebrick and the thickness of the wall is about 18 in. for the upper and middle sections and about 14 in. for the lower. The crucible is also usually lined with firebrick, although lately rammed-in coke or waste electrodes have been used with good success both in the bottom and in the sidewalls. The roof is lined with special shaped firebrick. To prevent it from raising, on account of the gas pressure within the crucible, an outside latticed steel construction suitably braced and connected to the shell plates is provided.

GAS CIRCULATION

The waste gases from the furnace are taken through either one or two openings in the throat. They are carried in gas conduits of sheet iron, with internal water sprinkling, to a large dust catcher, and from there to suitable washers and scrubbers for cleaning and cooling. The gas is drawn from the furnace through these apparatus by an exhaustor having a capacity of 1,700 to 2,800 cu.ft. per minute at 14-in. water gage. This exhaustor is direct connected to a 20- to 30-hp. totally inclosed variable speed motor. It is specially constructed to deal with the gas and has internal water-spraying appliances. A duplicate set is always installed in parallel for emergency, and one of them is periodically shut down for cleaning.

A portion of the gas is returned to the furnace by means of either one of the above-described exhaustors, or in order to assure a constant supply, by a separate rotary blower of the same capacity, but operating under a pressure of about 20-in. water gage. This gas is forced into the free space between the charge and the roof of the crucible, through a number of tuyeres in the wall. They are supplied from a bustle pipe and point upward to blow the gas directly underneath the roof in

order to cool it. There is consequently a certain quantity of gas circulating through the furnace, which is beneficial for the preheating of the charge in the shaft and for facilitating the preliminary reduction of the ores. The volume of this circulating gas is constant and the gas formed during the process is, therefore, available for heating auxiliary boilers or furnaces in the plant. For this purpose it is of particular importance on account of its high B.t.u. value.

ELECTRODES

The electrodes used are almost exclusively made of amorphous carbon and number from four to eight, depending on the capacity of the furnace. They are round, 24 in. in diameter, have nipple joints for continuous

FIG. 1. SECTION OF A TYPICAL SWEDISH ELECTRIC PIG-IRON FURNACE

feed and can be loaded up to about 16,000 amp. Heavy water-cooling boxes and gas glands are placed in the apertures where the electrodes enter the crucible roof and close to them are water-cooled contact clamps of copper directly connected to the busbar work. As the power input is regulated by changing the potential on the transformers, there is no need of electrode adjustment except as they are consumed. The feeding mechanism for that reason is extremely simple and consists only of a screw drive with handwheels. The electrodes are mostly supplied from Sweden or Germany; American makes have been used extensively, the price, however, being at present too high on account of prevailing

rate of exchange and the high freight rates. Graphite electrodes have been used successfully, although no figures on their cost are available in comparison with amorphous carbon. There is a possibility, however, that such electrodes will be necessary on account of their high current conductivity in larger furnaces requiring more power and where consequently a higher amperage must be carried.

COOLING SYSTEM

In addition to the electrode coolers and contact clamps, there are various other parts of this furnace that must be water-cooled. For instance, at the flexible joint between furnace shaft and crucible there is a water-cooled ring. In the shaft brickwork, at the tap hole, tuyeres, etc., there are water pipes and coolers in accordance with standard blast-furnace practice. Furthermore, most furnaces lately installed have a complete water-spraying device for the entire shell of the crucible. In addition water is required for cooling the transformers, exhausters, gas conduits and for cleaning the gas. It is, therefore, of utmost importance that an ample water supply be provided at suitable pressure and that the operation of the system be safeguarded against breakdown. For that reason centrifugal pumps are always installed in duplicate, each having a capacity of about 200 gal. per minute. In addition a tank of about 500 cu.ft. capacity is situated on the charging floor at a higher level than the furnace. This is desirable to provide against any temporary failure of the main supply pipes.

The crucible roof is air-cooled on the outside by means of blast supplied from a small rotary blower connected to a 5-hp. motor.

HANDLING OF SLAG AND IRON

Usually both cinder and iron notches are provided. For very rich charges, however, only the iron notch is used. The iron is run in launders to the pig beds, as shown in Fig. 2, or may be poured in a ladle for transportation to a mixer or bessemer converter. The slag is collected in large pots and the arrangements for tapping or handling iron and slag do not differ from general blast-furnace practice.

ELECTRICAL EQUIPMENT

The operating current for this type of furnace may be either two-phase or three-phase, depending upon the furnace capacity. The average size furnace has about a 3,000 to 4,000 kva. transformer bank, consisting of three single-phase transformers which are delta connected on primary. On secondary six independent phases are induced, each connected to one electrode, making a total number of six. Larger furnaces have two single-phase transformers which are Scott-connected for incoming three-phase, giving a two-phase, four-wire system. On secondary each conductor is then connected to two electrodes, making a total number of eight.

The transformers are installed as close to the furnace as possible in order to use a minimum amount of busbar copper and to avoid excessive current loss by induction. The transformers are specially constructed to withstand the heavy duty imposed upon them. The secondary voltage can be regulated in eight to nine steps, from 55 to 110 volts for charcoal, or from 35 to 70 volts for coke furnaces by means of reduced capacity taps on primary coils. The tap changing is accom-

plished under full load for each phase separately by means of eight-way primary selective break switches, remote operated with handwheels from outside the transformer room.

The transformers and the above-mentioned selector break switches, together with other electrical equipment required, such as main automatic oil-circuit breakers, lightning arresters, power transformers, etc., are all installed in a separate transformer room, which usually is an extension to the main furnace building. The secondary busbar leads are brought over from the transformers to the furnace interlaced and are directly connected to the contact clamps.

In order to cut down the cost of copper and the induction losses installations have also been made where one transformer unit is located directly in front of each pair of electrodes. Rotary fans are then necessary for cooling the transformers. This arrangement, however, is not practical from an electrical standpoint especially with respect to primary interconnections.

All instruments necessary for the electrical control of the operation are mounted on panels conveniently situated on a level with the roof of the crucible. The handwheels and handles for operating the primary switches are mounted on panels that fit into the wall of the transformer room.

The incoming primary current on the different Swedish installations varies from 6,800 to 20,000 volts and in each case is stepped down directly to the operating voltage of the furnace. The number of cycles does not seem to have much bearing on the matter, as there are installations on 25- and 50- as well as on 60-cycle current.

HEAT GENERATION

The heat in the furnace is generated by the passage of current between the electrodes and is proportional

FIG. 2. LOWER PORTION OF FURNACE AND IRON RUNNER

to the voltage between any pair of electrodes. The power input is regulated by changing the potential on the transformers, and the connections are arranged so that the transformers can operate without injury with different phase voltage. This is an important feature, as the power input is usually regulated according to ammeters or wattmeters which are connected to the secondary busbar leads for each electrode. The operator must endeavor to maintain an even power input for each electrode and must change the potential whenever necessary. As the resistance of the charge between the electrodes changes the potential has to be adjusted to maintain the same power input. Occasionally, however, the power at one electrode may have to be increased or decreased to obtain an even melting or sinking of the charge.

CHARGING FLOOR AND HANDLING OF ORE

It is of great importance in the operation of this type of furnace as on all charcoal blast furnaces that the charge of ore, lime and charcoal or coke be properly distributed in fixed quantities. For this reason a specially constructed gas-tight bell is used with double conical rings in which the charge is contained. The bell is discharged by means of a hoist by a double movement whereby the content of each ring is emptied separately. The hoist and winding gear for raising and lowering the bell is operated by a 4- to 5-hp. reversible and totally inclosed electric motor.

On one side of the charging floor are installed a number of ore bins provided with discharge gates, and the bell is charged by hand with a charging bucket. The ore bins should have a total capacity of from 70 to 100 tons per furnace. Fig. 3 is a view of the charging floor.

The ore should be crushed down to 2½ in. maximum size and preferably less. For this purpose crushers are installed on the ground level in a special building. Usually one gyratory crusher, driven by a 60-hp. motor, is sufficient, but for larger installations two or three crushers are employed. The crushed ore drops into a loading chute, then into an automatic skip, which discharges into a receiving hopper on the feed floor. From there the ore is distributed to the various bins by means of a larry-car, which can be spotted automatically.

For smaller furnace installations the skip hoist is usually replaced by an inclined bucket elevator, which unloads onto a belt conveyor with a tripper.

Some installations have also been made where the ore bins are located on the ground, in which case the prepared charge is hoisted up in a bucket to the charging floor and tipped into the bell.

CHARCOAL OR COKE STORAGE

Charcoal or coke should be stored in a special fire-proof building of concrete or steel construction, with walls and roof of corrugated iron, having a capacity of about a year's supply. After screening the fuel is loaded into buckets having a capacity of about 30 cu.ft. and transported to the charging floor of the furnace by means of an aerial tramway.

WORKING STAFF

The operation of the electric pig iron furnace requires the same class of labor as common blast furnaces. For an installation of two furnaces the follow-

ing force is necessary: One superintendent, one assistant superintendent, two chemists, three foremen, one electrician, one crane operator, eight common laborers per shift. In addition there will be required two men per shift for loading charcoal and from three to five men per shift for unloading and crushing the ore.

STARTING OF FURNACE

The furnace should be slowly pre-heated with a coke or wood fire in the crucible for about two to three weeks. After the ash is removed and 2 to 3 tons of coke is shoveled into the crucible through the electrodes holes about twenty charges of coke, ore and lime are filled in and the electrodes inserted. Carbon blocks are placed directly underneath each electrode to insure a good contact. The entire shaft is filled with charges of mixed ore, lime, coke and finally charcoal with slowly increasing ore content. The current is then switched on, but the gas circulation is not started until about two days after.

OPERATING DATA

Swedish ores are usually very rich in iron and consist of magnetites and black hematites in the form of lump ore or concentrate, either crude, briquetted or sintered. The various ores available are mixed with suitable fluxes, such as bessemer slag and lime, to obtain the desired slag. In general the charges will contain anywhere from 50 up to 60 per cent of iron. Fine concentrates can be used dry only and to a limited amount, the maximum being about 30 per cent. The reason for this is that they have a tendency to pack in the shaft and stop the circulation of gas, not only on account of their fine character but mainly because they easily flux and seem to attach themselves to the refractories. This may cause scaffolding with subsequent caving of the charge, serious disturbances in the furnace operation very difficult to overcome whenever they appear. (Increasing the gas pressure as a corrective would not be feasible, as the thin brick roof of the crucible would then give way.) The lime should be crushed to the size of a large walnut and usually does not have to be burned. In furnaces operating with coke, however, burning seems to be of some advantage.

Charcoal should preferably be of pine, in lump form and fist size. The fine material after screening can be used only with difficulty and to a very limited extent. Charcoal made of refuse from sawmills is not very suitable, as it contains mostly flat pieces that stop the gas circulation.

A typical analysis of Swedish charcoal is as follows:

H ₂ O.....	13.21	Ash.....	2.18
Gas.....	11.72	C.....	72.89

and the average weight is 40 lb. per hectoliter.

The consumption of charcoal is, of course, dependent on the ores and the operation of the furnace, but in general will amount to only 35 to 45 per cent of the requirement in a common blast furnace. It may be of interest to know that during 1918 the average consumption of charcoal in all Swedish blast furnaces was 56.6 hl. per ton, whereas in the electric pig iron furnaces it amounted only to 24.8 hl.

OPERATION ON COKE

In regard to the operation on coke very little data are available, although furnaces are now running in Norway using a mixture of coke and charcoal as re-

ducing agent. Trials made in Trollhättan led to the conclusion that the operation on coke was not satisfactory. This, however, was due to the fact that the furnace and equipment were not suitable for the purpose. Trials made in Tinfos and Hardanger, in Norway, showed that the dimensions of the shaft as well as the crucible had to be changed materially. Coke has a higher current conductivity than charcoal and furthermore tends to graphitize, for which reason the potential must be lower, and suitable taps on the transformers arranged accordingly. It may, therefore, be assumed that a properly designed coke furnace, with equipment provided for the purpose contemplated, may be a success. An interesting report on the results obtained with coke in furnace installations in Norway has been written by George Stig and appeared on page 29, July 7, 1920, issue of CHEMICAL & METALLURGICAL ENGINEERING.

It has been proved that the pig iron produced from these furnaces is of a higher grade than the iron from common blast furnaces. The reason is probably that

FIG. 3. VIEW OF CHARGING FLOOR

electric pig iron is more thoroughly deoxidized and, therefore, requires less content in Si and Mn to be suitable for the open-hearth process.

The iron and slag from electric pig iron furnaces are always tapped at a lower temperature than from common blast furnaces. This is contrary to what would be expected when using electricity for heating, but is due to the large capacity of the crucible. Directly underneath the electrodes the heat is, of course, intense, but in the center and bottom of the crucible and between the electrodes are fields where heat must be supplied by conduction. The cold gas and the effective cooling of the roof are also features that greatly contribute toward lowering the temperature so that the average will be comparatively low.

With an ample power input, however, the temperature can be considerably increased so that no trouble has been experienced, at least in later installations, in producing a pig iron high in carbon and silicon and with a gray fracture.

The operation of these furnaces is very simple and requires less labor than common blast furnaces, as long as no variations in the charge are made. Any alterations, however, in the amount of ore and coke must be carried out carefully, as the furnace will react very suddenly if the changes are made too violently and disturb the equilibrium in the crucible. It must also be borne in mind that the means to re-establish

normal conditions are very limited for this type of furnace. Usually the only remedy is to throw ore or coal into the crucible through openings in the roof, as a change in the charge would not have any effect until a long time after.

PRODUCTION OF GRAY IRON

On account of the intense heat of the arcs from the electrodes a certain amount of calcium carbide is formed, which evidently has a deoxidizing effect on the iron. This carbide slag will also eliminate some of the sulphur, although not to the extent that would be expected. As a matter of fact, the desulphurizing in these furnaces in usual practice is less than in the ordinary blast furnace, which, of course, is due to the lower temperature. However, with high-powered furnaces lately installed, sulphur has been successfully eliminated by an ample power input producing an iron of gray fracture and high silicon. It is, therefore, obvious that the introduction of carbon and silicon and the elimination of sulphur is a matter of using coke, power and time in the furnace, but can always be accomplished. High-sulphur ores, however, should be roasted not only to save power, but to avoid the large charge of lime that otherwise would be necessary and that would make the slag too basic and sluggish.

Most furnaces operate with a slag of about 1.4 to 1.5 silicate degree (a sesquisilicate), which is satisfactory, especially when the bottom is made of crushed coke. Preferably, however, the silicate degree should be lower and down to 1.0 (a singulo-silicate), in order to avoid bad corrosion from a more acid slag.

FURNACE GAS

The temperature of the gas extracted from the furnace is, of course, dependent upon the pressure obtained from the blower. On late installations, the temperature is about 400 to 550 deg. F. The dust contained in the gas was investigated in Trollhättan and found to be 4.63 g. per cu.m. gas (of 0 deg. C.) in the down-comers from the furnace shaft. To show the efficiency of the cleaning system, it may be of interest to know that after the washer and scrubber the content was reduced to 0.88 g. and in the bustle pipe to 0.62 g.

An average analysis of the gas from this furnace shows results as follows:

	Volumes Per Cent		Volumes Per Cent
CO ₂	23.49	CH ₄	1.52
CO.....	63.15	N.....	1.49
H.....	10.35		

The weight of 1 cu.ft. of dry gas was 0.081 lb. and the heat value 2,297 cal. per cu.m., which is equal to 258 B.t.u. per cu.ft. dry gas.

The gas circulation has been greatly improved lately by the installation of positive blowers that deliver a constant volume of gas. This was the key to the solution of a variety of difficulties, especially with respect to uniformity in operation.

REPAIRS AND RENEWALS

Late figures on electrode consumption are rather high, probably due to their war quality. Previous to the war it required from 11 to 15 lb. per ton of pig produced and the greater part of this consumption is due to the carbon dioxide of the gas being reduced by the incandescent carbon to CO.

In regard to the life of refractories, the weakest point

in the furnace is the crucible roof, parts of which must be renewed as they burn out during the course of operation. For a large furnace installation of five units during 1917, the total production of pig iron was 29,255 tons and the total quantity of brick used was 416 tons. For 1918 corresponding figures were 25,791 tons with 391 tons of brick and for 1919, 22,350 tons, consuming 380 tons of refractories.

A complete relining of the crucible roof can be accomplished in about 5 days, using a force of sixteen men, and a complete relining of the entire furnace will take about one month.

An installation of one furnace will utilize about 76 to 77 per cent of the power, whereas for several furnaces the load factor will increase and approximate 80 per cent. The power factor is, of course, dependent on the number of cycles, but will average about 90 per cent for 25-cycle current. The efficiency of the furnace is about 70 to 75 per cent, based on the experience with the Trollhättan installation.

ACTUAL RESULTS

The results obtained from the operation of these furnaces are naturally greatly influenced by local conditions at the various plants, as for instance the number of furnaces installed, the capacity and the power behind each unit, the kind of ore used and the character of the pig iron produced.

In the following table some actual results during the first seven months of 1920 are given from the operation of a large plant of several units, having a transformer capacity each of 3,000 to 4,000 kva.

	Furnace 3	Furnace 5
Total amount of ore used, tons.....	5,733.20	6,310.41
Total amount of lime used, tons.....	568.74	742.80
Total amount of ore and lime used, tons...	6,301.94	7,053.21
Total amount of charcoal, lb.....	2,957,440	3,112,640
Total amount of current, kw.-hr.....	9,576,200	9,001,700
Operating time, hr. and min.....	3,736 5	2,989 35
Idle time, hr. and min.....	167 45	97 25
Total time, hr. and min.....	3,903 50	3,087
Produced pig iron:		
Open-hearth, tons.....	365,670	3,483.275
Bessemer.....	3,307,585	
Total, tons.....	3,673.255	3,483.275
Relative figures:		
Electrodes, lb. per ton pig.....	17.6	19.3
Charcoal, hl. per ton pig.....	20.1	22.3
Electric current, kw.-hr. per ton pig.....	2,605	2,580
Average load in kw.....	2,565	3,020
Pig iron per day in tons.....	22.5	27.1
Per cent pig of ore charged.....	64.2	55.25
Per cent pig of total charge.....	58.3	49.40
Lime in per cent of ore.....	9.95	11.75
Idle time in per cent of operating time....	4.47	3.23

"Ton" means metric ton of 1,000 kg., equal to 2,205 lb. (approximately 1 long ton).

COST OF INSTALLATION

The total present cost in the United States of a complete electric pig iron plant with one furnace of 4,000-kva. transformer capacity is estimated at about \$150,000.

New York, N. Y.

Fire Destroys the Wilmington Leather Co.'s Plant

The plant of the Federal Leather Co., at Wilmington, Del., was practically destroyed by fire which started in some unknown way in one of the older buildings and quickly spread throughout the entire works. Eleven buildings and valuable stock of both raw materials and finished leather products were destroyed before the fire was got under control.

Steel Castings of High Strength and Toughness—I

A Chapter From a Forthcoming Book Giving Data on the Improvement to Be Expected After Properly Heat-Treating Steel Castings, With Illustrative Tests on Strong, Tough Castings Which Have Replaced Forgings on Gun Mounts

By FEDERICO GIOLITTI
Bessemer Medalist

IT IS useful to illustrate the great variety of results obtainable on various types of steel castings by applying the processes which have previously been studied in theoretical outline,* especially in connection with the differences existing between the effects of homogeneity quenchings and of mere homogeneity annealings. In order not to multiply the examples unduly, some of the more characteristic and, so to speak, typical instances will be chosen.

NORMALIZED MILD STEEL CASTINGS

A soft steel casting containing carbon 0.23 per cent, manganese 0.66 per cent, silicon 0.21 per cent, phosphorus 0.05 per cent, and sulphur 0.03 per cent was reheated at 850 to 900 deg. C. and allowed to cool very slowly, requiring about thirty-six hours to reach room temperature.

It showed the microstructure reproduced in Fig. 1 and physical properties shown in Table I determined by pulling a tensile test-piece 12 mm. diameter and 40 mm. long between reference points.

A prismatic test-piece 20 mm. square tested under static flexure broke at an angle of 130 deg. with a coarsely crystalline fracture reproduced in Fig. 4.

The same steel reheated during twelve hours at 800 to 850 deg. C. and left to cool, requiring ten hours to reach atmospheric temperature, showed the microstructure reproduced in Fig. 2 and somewhat better physical properties (Table I).

The tension test revealed a "mixed" structure containing part crystalline and part fibrous texture, as shown in Fig. 4. The static bending piece bent into a U shape.

Finally, another casting of the same steel—after undergoing the first treatment above mentioned—was reheated at 800 deg. C. during twenty minutes, quenched in boiling water, and finally drawn during one hour at 650 deg. C. Its properties, especially the ductility, as shown in Table I, are still better.

The microstructure of the steel thus treated is reproduced in Fig. 3. The fracture of the broken test-piece reproduced in Fig. 4 was entirely fibrous.

TABLE I. PHYSICAL PROPERTIES OF HEAT-TREATED 0.23 C STEEL

Heat-Treatment	Tensile Strength	Elastic Limit	Elongation	Reduction in Area
Reheated to 875 deg. C., cooled in 36 hr.	61,600	34,300	13	
Reheated 12 hr. to 825 deg. C., cooled in 10 hr.	68,000	41,000	17	13.9
Complex (see text)	73,600	47,000	17.5	24.8

The prismatic flexure test bent into a U, similar to the previous one.

EFFECT OF INSUFFICIENT ANNEALING

Another mild carbon-steel may be cited, made by the acid process and having the following composition:

	Per Cent
Carbon.....	0.25
Manganese.....	0.85
Silicon.....	0.15
Sulphur.....	0.02
Phosphorus.....	0.03

It was cast in ingots 15¾ in. (400 mm.) square. Fig. 7 shows the structure of this steel as cast. Rectangular bars 3½ x 5½ x 11¾ in. (80 x 150 x 300 mm.) were taken from the lower half of those ingots and subjected to the heat-treatments indicated in the first column of Table II. In the next four columns of the same table

FIGS. 1 TO 3
Structure of 0.23 C. steel casting after various heat-treatments.

*"Heat Treatment of Soft and Medium Steels," Press of McGraw-Hill Book Co.

Fig. 4. Fracture in static bending after very slow cooling.

Fig. 5. Tensile fracture after normalizing

Fig. 6. Tensile fracture after complex heat-treatment.

are noted the principal tests on tension pieces 13.8 mm. in diameter by 100 mm. long taken from the bar after being subjected to the heat-treatments indicated in the first column.

Heat-Treatment	Physical Properties				Structure (Enlarged 100 Dia.)
	Tensile Strength, Lb. per Sq. In.	Elastic Limit, Lb. per Sq. In.	Elongation, per Cent	Reduction in Area, per Cent	
Annealed at 940° C. during 45 min. followed by slow cooling in the furnace.....	79,600	42,700	17.5	18	Fig. 8
Annealed at 850° C. during 45 min. followed by slow cooling in the furnace.....	76,800	44,200	14	13	Fig. 9
Heated and cooled as No. 1 followed by a drawing at 700° C. during one hour and subsequent slow cooling in the furnace.....	73,200	39,800	21.5	27	Fig. 10
Heated and cooled as No. 2, followed by a drawing at 700° C. during one hour and subsequent slow cooling in the furnace.....	74,500	42,700	26	35	Fig. 11

The tabulated data particularly exhibit what has been said relative to new heterogeneities induced by recrystallization of ferrite from a system of austenite crystals in which the greatest part of the original chemical heterogeneities has been undisturbed by insufficient annealing. Inherited non-uniformities are especially evident in the large variations in ductility due to ferrite accumulations accentuated by the drawing operations. To be convinced on this point, compare structure and the figures for elongation and the reduction of area of the first and second test-pieces with the third and fourth.

LIMITED EFFECT ON VERY SOFT CASTINGS

In order to confirm the relatively limited effects which homogeneity heat-treatments produce upon the physical properties of very low-carbon cast steels which,

by the way, never present the real phenomena of ingotism, I may add in Table III some comparative data between the effects produced upon the physical properties of one of those steels by a pair of homogeneity quenches of considerable energy. The steel examined was of following composition:

	Per Cent
Carbon.....	0.09
Silicon.....	0.028
Manganese.....	0.47
Sulphur.....	0.01
Phosphorus.....	0.02

TABLE III. NORMALIZATION OF 0.09 PER CENT CARBON STEEL

Heat-Treatment	Physical Properties

Heated at 850° C. for 3 hr., followed immediately by quenching in water and then drawn at 650° for 2 hr.....	50,500	30,000	31.8	55.8
Heated for 14 hr. at 1100° C. followed immediately by quenching in water. Re-heated at 850° C. for 3 hr., followed immediately by quenching in water. Finally, drawn at 650° C. for 2 hr....	54,500	33,700	33	60.2

HOW INGOTISM EXHIBITS ITSELF

When steel is cast in quite large masses, either in ingots or in formed castings, the phenomena of ingotism always appear with a great deal higher intensity than when it is cast in smaller sections. This is due to the well-known fact that the slowness of cooling during the solidification range enhances the phenomena of intercrystalline liquation and segregation. Ingotism also shows a greater intensity when massive castings contain large quantities of emulsified inclusions. Evidently the steel then feels the effects of even a mild homogeneity heat-treatment a great deal more than it would were it cast in smaller masses.

As an example of this fact, take the case of an acid open-hearth steel having the following composition:

	Per Cent
Carbon.....	0.47
Manganese.....	0.63
Silicon.....	0.27
Sulphur.....	0.029
Phosphorus.....	0.03

Rough castings weighing more than ten tons each for 381 mm. gun cradles were made with this steel. One of these castings was heated for twelve hours at 750

FIGS. 7 TO 11

Structure of 0.25 C acid steel ingot after various heat-treatments. × 100. Etched with alcoholic solution of picric acid.

FIGS. 12 AND 13

Impact fractures of massive 0.47 C steel casting after different heat-treatments.

deg. C. Tension test-piece (cylindrical bars 13.8 x 100 mm.) and Charpy impact samples (30 x 30 x 160 mm., with a cylindrical notch 4 mm. in diameter) were then cut from the body of this casting.

The results of these first physical tests are contained in Table IV. The pulled test-piece was stretched throughout all its length, and the fracture of the impact bar revealed a coarsely crystalline structure, Fig. 12. These properties correspond well to the microstructure and are indicative of strong ingotism partly due to the presence of a large proportion of inclusions.¹

The same casting was reheated for seven hours at 850 deg. C. and then left to cool in the air, so that its temperature dropped to 400 deg. C. in about three hours. The effect of the heat-treatment upon the structure consisted of a remarkable dissemination of the massive ferrite. Equally remarkable are the effects upon the physical properties, as shown in the table.

The tension test-piece did not show the least stretching along its length which produces the characteristic dappled surface, and the impact fracture exhibited a

¹An extended contribution on the effect of oxidized inclusions in steel will be published shortly in CHEMICAL & METALLURGICAL ENGINEERING.

FIG. 14. TESTS ON RAW 0.21 C STEEL CASTING

finely crystalline and partly fibrous structure shown in Fig. 13.

These data well indicate the mechanical characteristics by which ingotism appearing in thick masses of cast steel exhibits itself, especially when the metal contains large quantities of emulsified inclusions. In fact we must conclude that the "normal" properties of this steel are still altered or disguised even after the long heating at 750 deg. C.; denoting by the term "normal" properties the average resulting from the superposition

TABLE IV. HEAT-TREATMENT OF MASSIVE CASTINGS CONTAINING 0.47 PER CENT CARBON

Heat-Treatment	Tensile Strength	Elongation	Charpy Impact, Kg.-M. per Sq.Cm.
Heated for 12 hr. at 750 deg. C.	76,200	19.0	1 2
As above, then reheated 7 hr. at 850 deg. C. and air-cooled.	88,000	24.0	3 61

of the specific properties of its individual normal structural constituents. Were this not the case, there can be no doubt that the effect of the second heating at 850 deg. C., followed by slow cooling, should have changed the physical properties of steel, in an *opposite*

FIG. 15. TESTS ON 0.21 C CASTING AFTER NORMALIZING AT 850 DEG. C.

direction to those which in reality it has produced. The above examples confirm the idea that the average properties as usually determined on steel affected by ingotism are most probably due to the distribution and the continuity of the structural constituents rather than to the specific properties of the constituents themselves.

TESTS ON SPECIAL STEELS

We should now sum up the conclusions we have reached regarding the results obtainable by various homogeneity heat-treatments when applied to castings for machine parts when manufactured of the types of steels more frequently used for such purposes.

In order to give examples which conform to normal industrial conditions, I shall select steels of the average purity usually attained in steel foundry operation. This observation holds not only for "structural" or (improperly called "metallic") impurities such as sulphur, phosphorus, copper, etc., but also for the "foreign" or "non-metallic" impurities, especially the solid inclusions.

Results will be given for the usual physical tests—i. e., tensile, static bending, and impact upon a nicked

FIG. 16. TESTS ON 0.21 C CASTING AFTER AIR-QUENCHING

bar. In addition to these it will be useful to add the results of a impact tension test, made by the well known method using Charpy's pendulum striking a fixture holding a cylindrical test-pipe 10 mm. in diameter by 50 mm. long between the conical heads. The breaking work will be indicated in kilogram-meters, and refers to the initial cross-sectional area of the test-piece. All the static tensile tests referred to in the following paragraphs of this chapter were made upon cylindrical test-pieces 13.8 mm. in diameter by 50 mm. between reference points. Static bending tests were made upon rectangular prismatic bars 9.5 x 20 x 160 mm. The test-pieces were placed horizontally upon one of its 20-mm. faces, upon two parallel hard steel rolls 70 mm. in diameter, spaced 140 mm. apart on centers, and free to turn around their axes. The test-piece was forced to bend by pressure imposed upon the upper face by means of a 40-mm. steel cylinder whose axis was placed parallel to the end supports and so arranged that it could move up and down a vertical plane passing midway between. Pressure was maintained until the two ends of the test-piece were bent enough to slip between the two supporting cylinders, so that at the end of the test the piece was bent like a U with almost parallel legs.

The examples to be mentioned in the following para-

graphs are especially interesting when the physical properties obtainable by means of simple homogeneity reheatings are compared to those resulting from homogeneity quenchings.

EFFECT OF CARBON

Starting with ordinary carbon steels for making castings, data relative to two steels containing 0.21 per cent and 0.34 per cent carbon are gathered in Tables V and VI. Merely for comparison, data obtained from forged test-pieces of the same steels have been added. Working was done at about 1,000 deg. C., bringing a square bar 100 x 100 mm. down to 35 x 35 mm. Pieces for the various physical tests were always cut from the forged bars in a *longitudinal* direction—that is to say, with their long axis parallel to the direction along which the steel had been extended by forging.

In the figures reproducing the appearances of the tension and bending tests the two tension tests shown on the left are those broken under a gradual pull, while the two at the right are those broken under longitudinal impact. The slow bend test is shown above in the center, while below is the fracture of the piece broken by the Charpy impact pendulum. These figures are reduced to about half natural size. Microstructure

is at an enlargement of 60 diameters, after etching with nitric acid in amyl alcohol.

Two steels, which will be indicated with the letter A and B respectively, had the following chemical composition:

	A	B
	Per Cent	Per Cent
Carbon.....	0.21	0.34
Manganese.....	0.94	0.96
Silicon.....	0.19	0.19
Sulphur.....	0.03	0.02
Phosphorus.....	0.07	0.06
Copper.....	Traces	Traces
Arsenic.....	Traces	Traces

Evidently they can be considered as differing only in carbon, inasmuch as the variations in all the other elements are within analytical accuracy.

It is easy to see that all the numerical data contained in the two tables, as well as all the structures reproduced in the fourteen corresponding figures, find a clear

FIG. 19. TESTS ON 0.34 C CASTING AFTER NORMALIZING AT 850 DEG. C.

previously, the present results were obtained by subjecting a casting of intricate form to various heat-treatments. For this reason the following data will give an idea of the results which can be readily obtained in the practical application of homogeneity heat-treatments.

Steel used for these experiments was made in the acid open hearth and had the following composition:

	Per Cent
Carbon.....	0.26
Manganese.....	0.90
Silicon.....	0.18
Sulphur.....	0.02
Phosphorus.....	0.04
Nickel.....	1.76

Twenty-three pieces like that detailed in Fig. 22 were cast from the same heat. Pieces for physical tests were taken from the thicker part of the wall of the partly square partly cylindrical bore shown in section in the lower right part of the drawing. The whole casting had previously been subjected to a given heat-treatment.

For information and as a datum, I might add that a bar taken from an ingot of the same heat, after being forged and reheated at about 850 deg. C., gave the following results in tension when using a cylindrical

FIG. 20. TESTS ON 0.34 C CASTING AFTER AIR-QUENCHING

FIG. 18. TESTS ON RAW 0.34 C STEEL CASTING

interpretation in the considerations developed in the preceding chapters.

The general fact may again be pointed out from the two examples that the differences between the effects produced by annealing and those produced by quenching are less remarkable the lower the carbon content, all other conditions being equal. For confirmation, compare the data contained in the tables and the corresponding half-tones.

Comparing the microstructure and the physical properties of the cast sample No. 3 (rapidly cooled in air and drawn) with those of the same steel when forged and annealed (No. 4) gives a concrete example of what has been said regarding the possible errors resulting whenever it is thought that the average homogeneity of all components in a steel can be judged on the basis of a microscopical examination which, in reality, reveals only the distribution of the carbon. In the present case, for instance, the results of the physical tests reveal a greater persistency of the original chemical heterogeneities in tests 3 of both steels than in tests 4, while the microstructure of tests 3 actually appears much more uniform than that of tests 4.

TESTS ON COMPLEX NICKEL-STEEL CASTING

Information will now be given for a nickel steel more responsive to homogeneity heat-treatments. Contrary to the experiments upon simple test-pieces described

TABLE VII. TESTS ON NORMALIZED CASTING OF MILD NICKEL STEEL

test-bar 20 mm. in diameter and 200 mm. long between reference points:

Tensile strength.....99,500 lb. per sq.in.
Elongation.....17 per cent.

The results of the physical tests made on castings subjected to various indicated heat-treatments are gathered together in Table VII. The numerical data contained in this table do not need explanation and find easy interpretation in the body of considerations developed in the previous part of the book. However, it is useful to point out that these data, especially when compared with those just given, clearly substantiate a phenomenon known to be related to the relative frequency of the centers of ferrite crystallization. Special steels of this type are characterized by centers of secondary crystallization closely packed together. It

FIG. 22. DETAILS OF NICKEL STEEL TEST CASTING

is therefore a great deal less dangerous to cool such special steels through the transformation range slowly, after a given homogeneity heat-treatment, than it is to do the same thing with an ordinary carbon steel. From this special point of view it is especially interesting to compare the differences between No. 2 and No. 3 of Table VII with the corresponding values contained in Tables V and VI.

(Part II will be published in a subsequent issue.)

Reparation of War Damages in the Pas-de-Calais District

The Pas-de-Calais district was one of the principal sufferers from the war. The amount of damage done, exclusive of the heavy losses to the mines, estimated on a basis of values in 1914, reached 325,000,000 fr., apportioned approximately as follows: Damages to real estate, 138,000,000; for tools and appliances damaged or removed, 122,000,000; for the destruction and requisitioning of raw materials, 54,000,000; and for the destruction or requisition of manufactured articles, 11,000,000.

As the greater number of the establishments damaged were completely destroyed, large sums will be necessary for the reconstruction of this department. Already the amount for clearing away alone has reached over 8,000,000 fr., and advances of all kinds accorded to industrial companies for war damages exceed 200,000,000 fr. Of this, 120,000,000 has been allotted in money for urgent reparations, the reconstruction of buildings, transportation, administration expenses and the direct purchase of machinery, raw materials, etc. Of 1,551 industrial companies damaged, 400 have been set going again and 16 per cent of the labor employed before the war is now re-employed again.

Most of the reconstruction work already done has been in those industries connected with the manufacture and use of construction materials. Although much affected by the lack of coal, the brick and tile factories and the limekilns and quarries are producing to their utmost. The products of these industries are being used as rapidly as possible in the rebuilding of the 66,000 houses totally destroyed and valued at 1,320,000,000 fr., and the 29,000 houses partly destroyed, valued at 290,000,000 fr.

French Beet and Sugar Output

The official forecast for the French production of sugar beets for the 1920-21 period, as recently published in the *Review* of the American Chamber of Commerce in France, is placed at 1,919,538 tons of beets, as compared with 1,130,907 tons for the previous year, or an increase of 69.7 per cent. Refined sugar production is estimated to be 244,260 tons, as compared with 143,328 tons in 1919-20. This represents an increase of 70.4 per cent.

The Rise and Development of the Electrolytic Alkali and Chlorine Industry in Europe—II

An Outline of the Electrolytic Cells Employed in the Electrolytic Alkali and Chlorine Industry of the United Kingdom, Germany, Austria, France, Italy, Switzerland, Russia and Belgium*

By JOHN B. C. KERSHAW, F. I. C.

Electrolytic Alkali and Chlorine Industry in Germany

AS STATED in Part I of this article, the first successful electrolytic alkali works was that started in the year 1890 at Griesheim, near Frankfort, in Germany, the cell used being a diaphragm type of cell patented by the Elektron Co. According to Lunge, the experimental work which led up to the design of the Elektron cell was initiated by three German electrical engineering firms in 1884, a common fund being raised for this research work. The success which crowned the effort gave the Germans a distinct lead for many years in this new branch of the chemical industry.

The original Elektron works, at Griesheim, started with only 200 hp., but in 1892 it was doubled in size. At this period the writer was studying chemistry at Bonn University, and while there he heard with great surprise that success had been achieved at Griesheim in the manufacture of alkali by electrolytic methods, for at this date no one connected with the older LeBlanc alkali industry believed in the practicability of the electrolytic processes.

The Griesheim works having proved the value of the cell and process, a larger works was planned at Bitterfeld, in Saxony, where extensive lignite deposits are

companies have not always been satisfactory, the orders for plant and machinery which have been placed with German firms and the demand for German chemists and managers to take charge of these works in France, Russia, Austria and other European countries have no doubt amply compensated for the cost of the original research work carried out between 1884 and 1888 by the Allgemeine and other German electrical engineering companies. According to the writer's own figures, there were in 1907 already nine works in operation using the Elektron cell and process, the aggregate power utilized in these being 18,800 hp. Allmand, in 1912, estimated the aggregate capacity of the Elektron works at 33,000 hp., and stated that the Elektron or Griesheim cell was the most important of its type in use in Europe at that date. Its success is ascribed chiefly to its simplicity of design and low costs for repairs and maintenance, since its current and energy efficiency are comparatively low. (See accompanying Table.)

THE GRIESHEIM ELEKTRON CELL

The following description of the Griesheim cell is based largely upon that given by Allmand in the works already referred to.

The cell (Fig. 9) consists of a rectangular iron vessel, steam-jacketed, and covered externally with some non-heat-conducting material. This outer vessel contains a series of inclosed porous cement boxes about 1 cm. thick, which contain the carbon or magnetite anodes, and themselves act as diaphragms.

The advantage of magnetite as anode material for electrolytic alkali cells is that the chlorine gas is obtained free from CO₂; and it is claimed also that magnetite electrodes have a life of two years, even under the unfavorable conditions obtaining in the Griesheim cell. The magnetite anodes are of cylindrical shape, and are cemented to the lids of the anode boxes.

The chloride of sodium or potassium used in these cells is introduced into the anode chamber in the solid state, by a pipe reaching almost to the bottom of the cell, and is used in the pure form. The walls of the outer vessel act as cathodes, and in addition pieces of sheet-iron are suspended between each couple of anode cells.

The anodes and cathodes in each set of cells are connected in parallel and a current of 2,200-2,500 amp. is employed. The working temperature is high (90 deg. C.) and the concentration of caustic soda obtained in the cathode chamber is low, owing to the low current density employed and to the action of the current upon the sodium hydrate as it is formed. The solution in the anode boxes is kept saturated with NaCl (or KCl) and the caustic alkali solution is drawn off intermit-

† This cell produces Na₂CO₃ not NaOH.

found, and this plant commenced work with 2,000 hp. in 1894, and was doubled in size in 1895.

The developments of the Elektron cell and process in Europe since that year have been remarkably rapid and have proved the value of being first in the field, for although the financial results of the subsidiary

*For Part I see CHEMICAL & METALLURGICAL ENGINEERING, vol. 24, No. 2, Jan. 12, 1921, p. 77.

tently from the outer compartment of the cell. The emf. used varies from 3.6 to 4 volts. This low voltage is due to the fact that only a comparatively low current density can be employed and that the conductivity is increased by heat. When producing a liquor in the cathode chamber containing 80 g. NaOH per liter, in

FIG. 9. THE GRIESHEIM OR ELEKTRON CELL

fact, the current efficiency of the cell is only 70 per cent. This can be raised to 80 per cent if liquor of only one-half of this strength is produced. The high temperature of the anode chamber causes the production of chlorates, which can be separated by crystallization when potassium chloride is being electrolyzed, since the potassium salt is not a very soluble product, but the sodium chlorate cannot be separated in this manner and is therefore lost.

The electrochemical works at Bitterfeld is operated entirely with electric power, derived from the very extensive beds of lignite which occur in the vicinity. The site of this works was chosen by the promoters because it was believed that the cheapness of the power would more than counterbalance the distance of the

FIG. 10. EXTERIOR VIEW OF THE ELEKTROCHEMISCHE WERKE AT BITTERFELD

FIG. 11. GENERAL VIEW OF BOILERS FOR BURNING LIGNITE IN GERMANY, WITH STEP-GRATES BELOW FLOOR LEVEL

works from the usual markets for the manufactured goods. Very few details of the power plant have been allowed to appear in print.

Air-dried lignite is finally burned under tubular boilers with step-grates. Fig. 11 shows a general view of the charging floor of the boilers. The grate is sunk below the floor level, and the lignite is tipped directly into the charging hoppers from the tip wagons, in which it is brought into the boiler house. A sliding door, divided into three sections, regulates the admission of the fuel to the grate of each furnace. The

FIG. 12. THE BILLITER-SIEMENS CELL

angle of the step-grate can be altered from the ground level. The whole of the lower part of the grate is inclosed and the admission of air is regulated by levers which open or close the doors in front of the under-furnace space. The air required for combustion is drawn through a system of pre-heating stoves. As the use of the step-grate causes a very gradual evolution of the gaseous matter of the fuel, little or no smoke is produced and a secondary air supply, though provided for, is seldom required.

Trials carried out with this equipment have shown efficiencies ranging from 67 to 69.71 per cent. When using a fuel having a low heating-value, from 2.66 to 3.01 lb. of water were evaporated per lb. of fuel, the rate of burning varying from 3.1 to 4.1 lb. per sq.ft. of heating surface.

THE BILLITER-SIEMENS CELL

This cell was patented in 1907 by an Austrian chemist, Dr. J. Billiter. The patent rights for Europe then passed into the hands of Siemens & Halske of Berlin.

FIG. 13. BILLITER-SIEMENS CELLS AT SPIRO & SOHNE PAPER WORKS, BOHEMIA

and the cell is now known as the Billiter-Siemens cell. Before the war it was in operation in two works in Germany, two in Austria and one in the United States.

The cell is of the submerged diaphragm type (see Fig. 12), but the diaphragm is placed horizontally and not vertically, and it lies practically on the bottom of the cell, resting upon the iron gauze which forms the cathode of the cell. Above the diaphragm are placed inverted boxes or bell-jars, constructed of cement or slate, cemented at their lower edges to the diaphragm and containing large horizontal graphite anodes. The anode chambers are provided with pipes for feeding in the fresh brine solution, for leading away the chlorine gas liberated and for heating the electrolyte. The diaphragm of the cell is formed of asbestos-cloth, covered on its upper surface with a mixture of asbestos wool and fine barium sulphate, which prevents convection and diffusion losses and yet possesses a low electrical resistance. This horizontal layer of fine but well-graded inert material is the novel feature of the Billiter diaphragm. The cathode net, with the diaphragm resting upon it, is bent slightly upward in order to permit the escape of the hydrogen formed on its under surface. Several of these anode boxes or bells are contained in the outer vessel, which may be square or oblong in shape.

At Aschersleben long, narrow troughs are employed, with granite side-walls and iron bottoms, which thus serve to make electrical contact with the cathode net resting upon them. There are ten cells, each designed to utilize a current of 2,000 to 2,500 amp. and to yield a caustic potash liquor containing 18 to 23 per cent, with an expenditure of 1,000 kw. The chlorine obtained from the cell is remarkably pure, and the current efficiency is as high as 95 per cent, with an emf. of only 3.66 volts per cell.

Another form of the Billiter-Siemens cell had

been introduced before the war at the sulphite paper-pulp works of Spiro & Söhne, at Krummau, in Bohemia. The cells are very much reduced in size from the earlier trough type. They are constructed of boiler-plate, with a thick cement lining along the four inner sides, in order to confine the current to the bottom of the cell. This bottom, as before, is in contact with the iron-gauze cathode upon which the diaphragm rests. Each cell contains twelve graphite anodes, connected in parallel, the cells themselves being connected in series. Each cell takes 500 amp. and the total power used in the thirty-two cells installed is 65 kw. The chlorine produced at this plant is absorbed by milk of lime and is used in the form of calcium hypochlorite solution for bleaching purposes. The caustic soda liquor produced is sold in the liquid form, as facilities for concentrating it and obtaining the solid product are lacking.

The only other type of electrolytic alkali cell in use in Germany before the war was the Solvay mercury cell,¹ at the works of the Deutsche Solvay Co., at Osternienberg. This works was started in 1896 and utilized 1,500 hp. for the manufacture of caustic potash and bleaching powder.

MANUFACTURE OF HYPOCHLORITE OF SODA IN GERMANY

As regards the manufacture of hypochlorite of soda by electrolytic methods in Germany, only two forms of cell have been used extensively—namely, the Haas & Oettel cell and the Kellner cell.

Electrolytic methods of producing bleaching solutions have been widely adopted in Continental Europe. Before the war many hundreds of these installations were to be found scattered all over the Continent, wherever cheap electric power was available. More recently the tendency in Germany has been to produce the chlorine in the ordinary type of electrolytic alkali cell and to absorb this chlorine in milk-of-lime before using the calcium hypochlorite as the bleaching agent. Siemens & Halske have convinced themselves, by actual trials, that this plan is the more efficient and economical. The high price of platinum has of course operated to prevent the further adoption of the Kellner electrolyzer, but the Haas & Oettel type is stated to be still employed in Germany, where sodium hypochlorite solutions are required for bleaching fine cotton or linen goods.

Electrolytic Alkali and Chlorine Industry in Austria

In Austria four types of cell have been employed for the electrolysis of brine solutions—namely, the Aussig bell type of gravity cell, the Billiter-Leykam cell, the Billiter-Siemens cell and the Kellner mercury cell.

THE AUSSIG GRAVITY CELL

In the Aussig gravity cell no diaphragm is employed to separate the anode and cathode compartments of the cell, but the greater density of the caustic soda formed at the face of the cathode is relied upon to effect its separation from the unaltered brine solution in the remainder of the cell. Fig. 14 shows a sectional elevation of the Aussig bell cell; *a* representing the anode, *c-c* the two sections of the ring-shaped cathode and *d* the bell which surrounds the anode and serves to collect the cathode gas. The successful operation of a cell of this type depends chiefly upon very careful control, not only of the specific gravity and of the rate

¹See CHEM. & MET., vol. 24, p. 79, where this cell is described.

of flow of the brine solution but also of the current density and of the relative positions of the electrodes to each other and to the lower edge of the bell.

The failure to study all the conditions required to obtain success with gravity process led to the failure of this type of cell at St. Helens in the years 1896-1900; but at the works of the Oest. Verein f. Chem. Produktion, situated at Aussig, the open bell cell has been in successful operation since 1899, and a current efficiency of between 85 and 90 per cent is said to be obtainable with it. The strength of the solution of caustic soda obtained runs from 100 to 150 g. per liter Na_2O .

The costs for maintenance and repairs are of course very low and the absence of a diaphragm reduces the emf. required to work the process to $4\frac{1}{2}$ volts. On the other hand, a low current density must be employed, and the bell can be constructed only of small dimensions, so that a large number of bells are required to produce a large output.

THE BILLITER-SIEMENS AND BILLITER-LEYKAM CELLS

The Billiter-Siemens diaphragm cell, which has been already illustrated and described,² was operated before the war at Bruckl, in Bosnia, by the Bosnische Elektrizitäts Gesellschaft, with sixty-four 2,500 amp. units, similar in type to those installed at Aschersleben.

FIG. 14. THE AUSSIG CELL

Dr. Billiter, however, in 1910, designed and patented another cell which dispenses with the diaphragm of his earlier type and is known as the Billiter-Leykam cell. According to Allmand, this was one of the most efficient cells that had been operated technically before the war. The cell is shown in Fig. 15 and is seen to be a modification of the Aussig bell type of gravity cell.

The chief feature of the cell is the design and arrangement of the cathodes underneath the bell-jar. These cathodes are constructed of T-iron, inclosed in woven asbestos bags or tubes, and are sufficiently inclined to allow the hydrogen to pass away readily by the opening marked 16 in the diagram; while the caustic liquor descends to the bottom of the cell, and passes away by the channel marked 4.

According to Allmand, it is unnecessary to purify the brine at all with this type of cell; and the asbestos sheath of the cathodes is woven as coarse as is consistent with its purpose of collecting and leading away

from the anode bell or hood the hydrogen gas formed underneath it at the cathodes. In this way all disturbance of the liquor within the bell by the escaping hydrogen bubbles is avoided.

The Austrian rights of this cell were purchased in 1911 by the firm of paper manufacturers, Leykam Josefthal Gesellschaft, and an installation of fifty-six 1,200-amp. units was started at its factory, at Gratwein, near Gratz, in 1912. Allmand visited this plant, which utilized 500 hp. in 1912, and has published a detailed description of it in a paper read before the Faraday Society in November of the same year. The current efficiency is about 92 per cent, and the emf.

FIG. 15. THE BILLITER-LEYKAM CELL

required at 65 to 70 deg. C. is $3\frac{1}{2}$ volts. The cathode liquors contain on an average 12 to 13 per cent NaOH; but by decreasing the rate of flow of the brine, 16 per cent NaOH can readily be obtained.

THE KELLNER MERCURY CELL

The Kellner type of mercury cell has been worked by the Consort. für Electrochem. Industrien at Golling, in Austria, and at Jaice, in Bosnia, since 1900; but again there is no information available as to what has happened to these works during the war period.

The first-named works was only a small one of 200 hp., but at Jaice, in Bosnia, there was a large hydro-electric installation capable of producing over 10,000 hp.

The Kellner mercury cell at both of these works differed from that used at Weston Point in that compressed air was employed to circulate the mercury. The cell was a large but shallow vessel, constructed of cement, and was divided into three compartments by transverse partitions, dipping into the layer of mercury on the floor of the cell.

The center compartment formed the anode division, and contained a number of cement hoods carrying the anodes. The two end compartments of the cell were the cathode compartments, and in these the decomposition of the sodium amalgam occurred with the aid of iron, exactly as in the original Castner-Kellner cell.

The cathode compartments were, however, provided with outside troughs in which the mercury collected, and by means of a pump this mercury was forced to travel backward and forward from the anode to the cathode compartment of the cell. The circulation is reported by Allmand to be very efficient, and to permit the use of a high current density with the cell (15 to 20 amp. per sq.dm.); but no other data concerning the operation of Kellner cell or of the works at Jaice are available for publication.

(The third and last part of the article, dealing with the Electrolytic Alkali and Chlorine Industry in France, Italy, Switzerland, Russia and Belgium, will be published in a subsequent issue.)

A Comparison of Various Methods of Water Purification

An Impartial Discussion on the Respective Merits and Disadvantages of Methods of Water-Softening by Filtration Through Zeolites, by Chemical Precipitation and by Rectification With Boiler Compounds

By WILLIAM MACKLIN TAYLOR

IN THE face of the claims and counterclaims set up by the manufacturers of the various processes of water purification, the layman and the chemist who have not specialized on this subject frequently experience difficulty in deciding which process is best adapted to their needs. The purpose of this article is to outline the strong and the weak points of these processes, drawing conclusions which will enable the uninitiated to decide more intelligently which process will solve his problem most successfully.

The term "water purification" is susceptible of two entirely different meanings. Water may be purified from a sanitary viewpoint and still remain as impure as before from an industrial standpoint, and *vice versa*. This article will deal exclusively with the purification of water for industrial uses.

Broadly speaking, the purification of water for industrial purposes may be divided into five classifications, which are as follows:

Distillation.

Removal of suspended matter by filtration.

Water-softening by filtration through zeolites.

Water-softening by precipitation.

Rectification by the use of boiler compound.

This article will deal principally with the last three methods mentioned and will touch on the first two very lightly.

DISTILLATION

Wherever a water of highest purity is an imperative requirement, distillation is the only method whereby it can be produced. The cost of its production is so high, however, that its commercial use is very limited, as compared with the other methods of purification. Where the entire absence of all impurities (dissolved and suspended) is not an absolute requirement, it is frequently possible, by the use of one or more of the other methods of purification, to obtain a water which will satisfactorily meet the requirements, and thereby effect a marked economy.

FILTRATION

Generally speaking, when a filter has removed all of the suspended matter which a water carries, it has fulfilled its mission. The processes of filtration are too well known to justify taking the time to describe them in detail here.

There are cases where filters which would hardly fall into the third classification are used for other purposes than the removal of suspended matter. The most notable of these are the filters whose beds are composed of marble chips, whose purpose is the removal of free acid from acid waters, and the filters whose beds are composed of various forms of charcoal, whose purpose is the removal of organic coloring matter.

The water in the clouds is as pure as any natural

water can be; but in passing through the air, as it falls in the form of rain, it commences to absorb impurities. As it travels over or through the earth before being used, it absorbs other impurities. The most troublesome of these are the salts of calcium and magnesium; and there is no natural supply of water known which is entirely free from them.

In cleansing operations as carried on in laundries and textile mills, the calcium and magnesium present in the water destroy soap, necessitating the use of larger quantities than would otherwise be necessary, thereby increasing the costs of operation. They form an insoluble curd-like precipitate with the soap, which adheres very tenaciously to the fibers of cloth or yarn and which causes trouble in various ways. In the laundry it causes a dirty yellowish gray appearance on the finished work, and later the organic acid to which the calcium and magnesium are united decomposes, giving off an unpleasant odor. In the textile mill it causes unevenness and breakage of the yarns in weaving, increasing the amount of "seconds." In the dye-house it forms lakes with the dyestuffs, causing streaked and uneven dyeing. In the preparation of certain chemicals, dyes, extracts, etc., the presence of calcium or magnesium salts causes precipitates, or lowers the quality of the finished product in other ways. In the boiler room the presence of calcium and magnesium in the water is a sure forerunner of boiler scale, which, if allowed to accumulate in the boiler, causes an enormous loss of heat and thereby a proportional excess consumption of coal. By acting as a heat insulator on the wrong side of the boiler shell, it allows the metal to become overheated, shortening its life and increasing the repair bill.

Hence, from the standpoint of nearly every industrial user of water, the salts of calcium and magnesium are trouble-makers and their elimination is desirable. Since it is these salts that make water hard, their elimination renders the water soft.

There are two well-known processes by which these salts may be more or less completely removed from the water. They are: Water-softening by filtration through a zeolite filter, and water-softening by precipitation.

ZEOLITE FILTERS

There are several kinds of zeolites in use today; some are of natural origin, some are produced by the fusion of several components, and others are produced by a precipitation process. All, however, work upon the same principle, taking advantage of the same chemical law of mass action, the details of operation alone being different. It is not my purpose here to state any preference for one over another, for all do good work and efficient work in the fields to which they are adapted.

In general, the zeolite water-softener is a pressure

filter, whose bed consists of granules of a zeolite. This zeolite is usually a hydrated silicate of aluminum carrying a large amount of loosely-bound and chemically active sodium. By the law of mass action, when water containing salts of calcium and magnesium is passed through this bed of zeolite, the sodium is exchanged for the calcium and magnesium, and the water in the effluent contains only very small amounts of the substances. If we use "R" as the symbol of the acid radicals to which the calcium and magnesium are joined, and "Z" as the symbol of the zeolite, the reaction which takes place might be written as follows:

This reaction, while very efficient from a commercial standpoint, does not proceed to theoretical completion, for a very small amount of calcium and magnesium remains in the filtered water, this amount usually ranging from 0.3 to 1.4 grains per gal., calculated to calcium carbonate. Water carrying less than the latter figure is usually referred to by manufacturers of zeolite water-softeners as water of zero hardness, although this term is really misleading.

In the author's library of water analyses, compiled during many years of work as a chemical engineer specializing on water purification, there appear many analyses of waters treated by the zeolite process. Some of these are accompanied by analysis of the same water before treatment. Probably the most representative of these is a sample of the city supply of Des Moines, Ia., taken July 3, 1917, and completed July 7, 1917. It runs as follows:

Dissolved Substance	Raw Water	Treated Water
Sodium chloride.....	0.58	0.88
Calcium carbonate.....	9.50	0.25
Magnesium carbonate.....	5.29	0.21
Magnesium sulphate.....	0.42	
Sodium carbonate.....		17.44
Sodium sulphate.....	8.52	8.59
Iron and aluminum oxides.....	0.40	0.14
Silica.....	1.14	1.24
Total.....	25.85	28.75
Hardness, calculated to calcium carbonate.....	16.15	6.50
Alkalinity, calculated to calcium carbonate.....	15.77	16.94

It is obvious that the time soon comes when all of the available sodium in the zeolite has been given up in exchange for the calcium and magnesium, and an exchange can no longer take place. When this time comes, it is not necessary to replace the zeolite with new material, for it can be regenerated or restored by reversing the law of mass action, for this law operates equally well in the reverse direction. This is accomplished by soaking the filter bed in a strong solution of brine made of common salt. The calcium and magnesium which had been absorbed by the zeolite are exchanged for the sodium of the sodium chloride, forming calcium and magnesium chlorides, and the sodium is absorbed by the zeolite. After having been steeped for a sufficient length of time—which differs with the products of different manufacturers—the brine is drawn off, the free salt remaining is rinsed out till the water runs sweet, and the zeolite is again in its highly effective state.

Water which has been passed through a zeolite water-softener exhibits the following properties:

It contains a smaller amount of calcium and magnesium salts than does the water treated in any other way except distillation.

It contains a slightly higher amount of dissolved solids than the raw water.

The alkalinity to methyl orange is slightly higher

and (except in case of an improperly-processed zeolite) no caustic alkalinity is added to the water. It makes a very satisfactory potable water and possesses a quite acceptable taste.

The greatest fields for the zeolite water-softener are in places where water is used for cleansing, as in laundries, textile mills, hotels and homes; or where the presence of the calcium and magnesium salts in the water cause trouble, as in the preparation of certain chemicals, extracts, dyes, etc.

PRECIPITATION WATER-SOFTENERS

The forms of precipitation water-softeners are many, but the principle upon which they operate is the same in all: The removal of calcium and magnesium salts by precipitation and filtration. The calcium is precipitated as the carbonate, the magnesium as the hydroxide. With few exceptions, the reagents used are hydrated lime and soda ash, and the precipitations are effected in accordance with the following reactions:

Some precipitation water-softeners have been sold which use caustic soda alone as the precipitant, but these had a very limited field, and never attained a very wide distribution. Other precipitation water-softeners at present on the market make use of barium carbonate as a precipitant in place of soda ash. These are valuable where the water contains large amounts of sulphates; but these constitute a special case, and cannot be considered at length here.

Precipitation water-softeners may be divided into two major classes: the intermittent and the continuous systems.

The continuous type of lime-soda ash water-softener (which enjoys a very much wider distribution than the intermittent type) consists usually of a large sedimentation tank provided with reagent tanks in which the weighed amount of chemicals to be used in treating the water is stirred up with a sufficient amount of water to permit of ready flow; and an apportioning device which allows the reagents to flow into the raw water in proportion to the raw-water flow. The water usually flows into a downtake, where it is thoroughly mixed with the chemicals and where the precipitation takes place. It then rises slowly in the sedimentation tank proper until it reaches the top, where it overflows through a filter, and is then ready for use. The sedimentation tank is built sufficiently large to allow such a slow upward movement of the water as not to interfere with the downward movement of the precipitates formed, as they settle in the form of a sludge, to the bottom, where they are drawn off through a valve as often as may be necessary. The standard practice is to allow four hours' time for the water to pass through this tank—i. e., the sedimentation tank is built sufficiently large to accommodate an amount of water equal to four times the rated hourly capacity.

The intermittent type of lime-soda ash water-softener consists of two or more large tanks from which the water is drawn alternately. As soon as one of the tanks is empty, it is refilled with the raw water, the necessary

amount of reagents is dumped in, and after a short period of agitation the precipitate is allowed to settle to the bottom. While this precipitate is settling, the water is being used from the other tank or tanks and by the time the supply of softened water in the other tanks is exhausted, the precipitate in the first tank is completely settled, and the water in this tank, now softened, is ready for use.

Water from the lime-soda ash water-softener exhibits the following properties:

It contains a smaller total amount of dissolved salts than the raw water.

Its alkalinity to methyl orange is usually less (except in cases of a raw water carrying a very small carbonate content), but it exhibits a small amount of "caustic alkalinity" (alkalinity to phenolphthalein). This is usually sufficient to give it a rather unpleasant, soapy taste, rendering it unfit for potable use.

It is impossible to carry the elimination of calcium and magnesium salts to the degree attained in the zeolite water-softener, the lowest practicable limit being a little over 1.6 grains per gal. of hardness, expressed in terms of calcium carbonate. In practice, the hardness of the treated water will usually run considerably above this figure, the average probably being in the neighborhood of from 3.5 to 4.0 grains per gal. The analyses which follow are those of raw and treated water from the city supply of Cedar Rapids, Ia., and are representative of the best results to be obtained from the lime-soda ash water-softener:

Dissolved Substance	Raw Water	Treated Water
Sodium chloride.....	1.46	1.46
Calcium carbonate.....	7.45	2.15
Magnesium carbonate.....	3.07	0.84
Magnesium sulphate.....	1.74	
Sodium carbonate.....		2.33
Sodium sulphate.....	8.05	10.22
Iron and aluminum oxides.....	0.11	0.12
Silica.....	0.71	0.79
Total.....	22.59	17.81
Hardness expressed as calcium carbonate.....	12.55	3.15
Alkalinity expressed as calcium carbonate.....	11.10	5.25

The greatest fields available for the lime-soda ash water-softener are in the treatment of water which is evaporated for steam and of water which is used for the production of raw-water ice.

BOILER COMPOUNDS

During the past two decades the use of boiler compounds has fallen into disrepute, due to two causes. Of these probably the more important has been the existence of manufacturers of unscientific formulæ—the charlatans and mountebanks of the water-purification field. The substances used in the manufacture of these compounds are legion, and they include such irrational and worthless components as sawdust, potato peelings, ground straw, malt, spent tanbark, etc. As a warning against these, I would advise every purchaser of boiler-compound to shun any compound which is claimed to give satisfactory results on every water. It is the same proposition to try to treat every human ailment with the same medicine as to treat every water with the same compound.

The other cause for the disrepute into which the use of boiler compound has fallen is the propaganda distributed by the manufacturers of water-softeners. The unscrupulous manufacturers referred to in the previous paragraph gave good grounds for this propaganda, but it was not directed solely against these. Many manufacturers of boiler compounds approach the problem of the prevention of boiler scale in a thoroughly scientific

manner, maintaining well-appointed laboratories where the work is carried on by experienced chemical engineers and where the problem of the proper treatment of water is worked out with intelligence and skill.

In considering the various methods of water-purification, it is these latter boiler compounds to which I shall refer.

Exactly what takes place in a boiler under the combined effects of heat and pressure we shall never know. We can only judge from results as seen from the outside and from interior inspection after the heat and pressure have been removed.

It has been learned that the presence of certain salts in the water causes scale and the addition of certain chemicals will prevent this, causing substances which would otherwise form the scale to settle to the bottom of the boiler in the form of mud, to be disposed of in the blow-off. Certain other dissolved salts have been found to induce foaming and priming. The addition of other chemicals has been found to exert a counteracting force. The number of chemicals used in the boiler-compound field are many. A few of those used for the prevention of scale by a precipitating action are: soda ash, caustic soda, sodium silicate, tri-sodium phosphate, hydrated lime, barium hydrate, barium carbonate, barium chloride. Other chemicals which prevent the adhesion of scale by causing it to form in granules or in some other way preventing its fastening itself upon the metal are: certain mineral oils, graphite and certain tannin extracts. Some of those which have a tendency to counteract foaming are barium hydrate, barium carbonate, barium chloride, hydrated lime and certain vegetable oils.

To neutralize corrosion from free acid or from the sulphates of iron and aluminum, any alkaline salt may be used, soda ash probably being the most frequently employed. Electrolytic corrosion may frequently be overcome by the use of metallic zinc.

In general, the only field for the use of boiler compounds is in the treatment of boiler-feed waters.

GENERAL DISCUSSION

The value of any of these systems of water-purification depends entirely upon two considerations: 1. The nature and amount of dissolved matter present in the raw water. 2. The purpose for which the water is to be used.

There are supplies of water which cannot be satisfactorily treated for any industrial use by any method with which the author is familiar; as for instance, samples of water from parts of North Dakota and Wyoming which he has analyzed and which contain magnesium sulphate in excess of 1,200 grains per gal. Some supplies can be successfully treated by one method where another method would fail utterly. It is the purpose of this article to help the engineer decide which method will give best results on his supply of water, for his purpose.

ADVANTAGES OF ZEOLITE TYPE OF WATER-SOFTENER

Let us consider first the zeolite type of water-softener. Its outstanding advantages are the following:

1. It produces a water which contains a smaller amount of calcium and magnesium salts than can be obtained by any other method except distillation.
2. It requires less expert attention than the lime-soda ash water-softener.
3. No chemicals are fed into the water, hence there

is no changing of amounts of chemicals to take care of fluctuations in the hardness of the water.

4. The only reagent used is common salt, and this is less subject to fluctuation in supply and price than is soda ash.

5. Because no sedimentation tank is required, the zeolite water softener requires less space than the precipitation water softener.

DISADVANTAGES OF ZEOLITE TYPE

Its outstanding disadvantages are as follows:

1. The amount of sodium salts present in the water is increased and (due to the fact that sodium, a monad, has an atomic weight greater than half that of either calcium or magnesium, both of which are diads) the total amount of dissolved matter is increased rather than diminished. If used for boiler-feed water, this would increase the tendency to foaming and priming.

2. The cost of operation, exclusive of the cost of labor, is greater than with the precipitation water-softener.

3. The capacity fluctuates with the fluctuation in the amounts of calcium and magnesium salts present in the water.

4. Disintegration of the zeolite by attrition and solution, although it may be very slight, increases the upkeep or depreciation of the installation.

5. Many waters that could be easily handled by the lime-soda ash water-softener cannot be handled by this system. Large amounts of calcium or magnesium salts or large amounts of sodium salts render its use either inefficient or impossible. A zeolite softener cannot satisfactorily handle any water containing a larger amount of iron than the average. The presence of minute quantities of manganese will in a short time render a zeolite softener incapable of softening water. If the raw water carries an appreciable amount of suspended matter, it must be filtered before passing it through the zeolite machine.

It is not my intention to weigh these advantages against the disadvantages for specific applications, but rather to point out a few general considerations governing their operation.

TYPE OF LAUNDRIES, TEXTILE MILLS, ETC.

In laundries and textile mills, where the presence of calcium and magnesium salts causes the destruction of soap, and the curds formed by the interaction taking place between soap and these salts cause a lowering of the quality of the work turned out, for the average water the zeolite system is the logical system to use. In the preparation of chemicals, dyes, extracts, etc., where calcium or magnesium causes precipitates or lowers the quality in other ways, the zeolite system is the better system, provided only that the presence of increased quantities of sodium salts does not affect the quality. This rule holds good only for waters whose hardness is not greatly in excess of the average. For a water whose hardness ranges above about 40 grains per gal., the advisability of installing a zeolite softener presents a special problem which would have to be decided separately for each separate case. The reason for this lies principally in the fact that the raw water used to rinse out the salt used for restoring or regenerating a zeolite must be used in such quantities that with such a hard water the tendency is to reduce the capacity of the softener beyond the economical point.

Where a water contains a large amount of sodium salts, there is a tendency for the law of mass action to act in both ways during the passage of the water through the filter bed. It is as if the upper layers of the zeolite removed the calcium and magnesium, and then the water with the addition of the sodium which replaced the calcium and magnesium, being so high in sodium salts, partially restored the zeolite in the lower layers, just as the brine does. The amount of sodium salts which would cause trouble varies in different cases, and it would be difficult to formulate any rules which would hold good in all cases. The presence, however, of more than 40 grains per gal. of sodium salts or of more than 50 grains per gal. of dissolved solids is sufficient to cause the water to be viewed with suspicion.

Where a water carries a higher amount of iron than usual, or even a minute quantity of manganese (this latter is comparatively rare), or where the water contains any free acid, it is necessary to pre-treat the water before passing it through the zeolite machine. Iron or manganese dissolved in the water is absorbed by the zeolite, and in time forms a coating over the granules which interferes with the contact between the water and the zeolite; and without this contact, the exchange of the sodium for the calcium and magnesium is impossible. Free acid present in the water causes the zeolite to disintegrate more rapidly than is the case with the normal, slightly alkaline water. In addition to this, the acid water which does not carry a comparatively high amount of dissolved iron is indeed a rarity. Acid waters, however, are rarely met with outside of districts where mining is carried on or where steel mills are located.

WATER SHOULD BE ANALYZED BEFORE DECISION IS MADE

This may be a good place to state that it is a wise move on the part of a prospective purchaser of not only the zeolite but of any type of water-purification apparatus to have an analysis made of his water by some responsible laboratory. If the proposed installation is a large one, the prospective purchaser can well afford to protect his interests by obtaining the opinion of a reputable consulting chemical engineer; for it will frequently mean the prevention of costly trouble in the end, compared with which the consulting chemical engineer's fee would be a mere trifle.

In many cases zeolite water-softeners have been installed in private homes, in apartment buildings and in hotels and have given complete satisfaction, water treated in a zeolite machine having a pleasing flavor, and the removal of the hardness makes the water much pleasanter to use for bathing or for any cleansing operation, besides leaving the skin in better condition. Some claims have been put forth to the effect that boiled foods will cook more quickly in softened water than in the raw water, but I question it.

ADVANTAGES OF PRECIPITATION WATER-SOFTENER

Now let us turn to the precipitation water-softener. Its prominent advantages are:

1. Lower cost of operation. Ignoring the question of labor (for the grade of labor used to operate the softener varies so widely with different owners of water softeners that a just comparison is impossible), with rare exceptions, the lime-soda ash water-softener can be operated at less cost per thousand gallons of water treated than is the case with the zeolite softener.

2. Capacity remains the same, regardless of fluctuation in the hardness of the water. The fluctuations are taken care of by increasing or decreasing the proportion of chemicals to the amount of water treated.

3. The treated water carries a smaller amount of dissolved solids than the raw water and there is not as great an amount of sodium salts added to the water as with the zeolite softener. This lessens the tendency to foaming and priming, when the water is used for boiler feed.

4. There is no depreciation on account of attrition of mineral, as with the zeolite water-softener. Given equal care, the life of a precipitation water-softener should exceed that of the 100 per cent performance of the zeolite filter bed.

5. The limits of hardness or amount of sodium salts present in water which can be treated are considerably higher than with the zeolite water-softener.

6. If the water contains an appreciable amount of suspended matter, it is not necessary that it be filtered before being treated.

7. Waters containing free acid or high amounts of iron or manganese can be as effectively treated as if these substances were not present.

DISADVANTAGES OF PRECIPITATION WATER-SOFTENER

The notable disadvantages of the precipitation water-softener are:

1. Where space is an item, the precipitation water-softener requires a much larger space than does the zeolite softener.

2. It is an impossibility to produce as soft a water as can be produced in the zeolite softener.

3. Its operation is more complicated than that of the zeolite softener; hence it requires greater intelligence on the part of the operator to make the changes in the treatment necessitated by fluctuations in the hardness of the raw water.

4. The soda ash used fluctuates in price, and is frequently difficult to obtain at any price.

5. It is difficult to obtain a water through a lime-soda ash water-softener that will be suitable for human consumption.

The water obtained by treatment through the precipitation water-softener is pre-eminently a water suitable for boiler feed or for the manufacture of raw-water ice. Prior to the commercialization of the zeolite water-softener, the precipitation system secured a wide distribution among laundries, textile mills, etc. But for ordinary waters, the zeolite water-softener soon demonstrated its superiority in these fields. In laundries and textile mills every grain per gallon of hardness left in the water represents the destruction of soap and the formation of the sticky curd caused thereby, and the fact that a softer water can be obtained with the zeolite water-softener enabled it to appropriate these fields almost exclusively to itself in territories whose water supply was not impossible of treatment by this method.

In boiler feed, however, it is not necessary that the water be softened down to the last grain per gallon in order to prevent boiler scale. The presence of a small amount of caustic alkalinity (alkalinity to phenolphthalein) in the water is not only sufficient to prevent the formation of new scale by the treated water, but it will also, in most cases, help soften and remove scale that had already formed. It is necessary, however, to watch the performance of the precipitation water-

softener quite carefully to see that the water is treated properly, and that the treated water conforms to the standards of tests for such a treated water. Any fluctuation in the amount of proportions of the dissolved solids calls for a corresponding change in the amount or proportions of the chemicals fed to the water. The standard practice calls for hardness slightly less than the alkalinity to methyl orange, and for the alkalinity to phenolphthalein to be slightly greater than half that to methyl orange. The hardness may reach 5 to 6 grains per gal. in the treated water without causing scale to form.

Laundries, textile mills and other users of water whose supply is of such a nature that the zeolite water-softener cannot handle it properly may frequently obtain very satisfactory results by the use of the precipitation water-softener. As a matter of fact, one distinction between the performance of the two types of water-softeners is the fact that the zeolite machine's efficiency (within reasonable limits) increases in reverse proportion to the hardness of the water, while that of the precipitation type of machine (within reasonable limits) increases in direct ratio to the hardness of the water.

In the manufacture of ice, the smaller the amount of dissolved solids present in the water the better is the water for freezing and the less will be the necessity for core-pulling. Water treated in the precipitation water-softener contains a smaller amount of dissolved solids than does the raw water, hence the value of the precipitation water-softener in this industry. Water treated by a zeolite water-softener will contain a larger amount of dissolved solids than does the raw water, hence the zeolite machine is of no value here. This is one case where there can be no argument as to the relative values of the two types of water treatment.

There remains now the question of the relative value of water treated by boiler compounds to that treated by water-softeners. As indicated above, the only field where boiler compounds come into competition with water-softeners is in the treatment of water for use in boilers to make steam.

ADVANTAGES OF BOILER COMPOUNDS

The principal advantages of boiler compounds are:

1. No expensive apparatus is necessary for the treatment of the water.

2. It is much simpler and easier to handle than is treatment through water-softeners.

3. More accurate proportioning of chemicals is possible.

4. A greater variety of chemicals may be used, effecting better results with many waters than could be obtained by the use of a water-softener.

5. There is no loss of water due to disposal of sludge, backwashing filters, etc.

DISADVANTAGES IN THE USE OF BOILER COMPOUNDS

The more prominent disadvantages in the use of boiler compounds are:

1. Difficulty in obtaining uniform treatment of all the water used.

2. The amount of mud collecting in the boiler is increased, rendering more frequent blowing-down necessary.

3. Actual cost per thousand gallons treated is usually greater than is the case with softened water. This is to some extent offset by interest on investment in a softener, depreciation, repairs, etc.

The salesmen for water-softeners are prone to consider boiler compounds as more or less of a joke, an unscientific way of treating water—making a water-softener out of the boiler. And, as has been intimated before, there are frequently good grounds for this attitude.

The scientific boiler compound of today, however, is really an efficient method of treating boiler-feed water, and in many cases a more scientific method than by treating the water through a water-softener, for there are frequently cases where conditions are met with which cannot be effectively handled with a merely softened water. Among these are the conditions which cause foaming and priming. The use of a water-softener will not prevent these troublesome conditions; water treated in a zeolite water-softener has an increased tendency to cause foaming; and in a water exhibiting a tendency to foaming great care must be taken in treating it with a precipitation water-softener, for the slightest over-treatment increases this tendency. On the other hand, an intelligently prescribed boiler compound will introduce chemicals into the boiler which have an active anti-foaming effect, and will actually prevent foaming.

Pound for pound, boiler compounds cost considerably more than the chemicals used for treating in a precipitation water-softener, but under the influence of heat and pressure the chemicals used carry the reactions which take place nearer to completion and a smaller amount of chemicals can be used to secure a similar effect.

Boiler compounds will have a palliative effect on waters which cannot be satisfactorily treated in either the zeolite or the precipitation water-softener.

On account of the fact that the precipitation takes place inside the boiler, it is necessary to keep closer watch on the blow-off and to prevent accumulations of mud on the flues and other heating surfaces of the boiler, for such accumulations would allow overheating of the coated surfaces which would render repairs necessary.

PRECAUTIONS TO PREVENT CORROSION

Corrosion is usually met with in cases of acid waters. This may be as easily remedied by the use of boiler compound as by treatment in the precipitation water-softener. Soda ash is frequently the neutralizing agent employed, although in many cases where the acid present is sulphuric acid, barium carbonate or hydrate is used. This eliminates the danger of foaming which the formation of an excess of sodium sulphate would cause.

Corrosion from electrolysis is a matter of occasional occurrence in stationary boilers. In marine boilers it is nearly always present. It has been found that the use of metallic zinc will overcome corrosion by electrolysis. When metallic zinc is present in the boiler, the zinc, being electro-positive to the steel of the boiler shell, acts as the anode and is corroded in place of the steel. This fact is made use of by one manufacturer of boiler compounds by using finely pulverized metallic zinc mixed in the compound.

METHODS TO INSURE TREATMENT OF ALL THE WATER

In order for boiler compounds to do their work effectively, it is necessary that all of the water shall be treated. This is frequently difficult of attainment. Some manufacturers make their compound in the form

of a liquid and snuff it in through the injector at stated intervals. Others manufacture their compounds in the form of bricks or of balls, and feed it through some device whereby a small stream of the water is diverted through a section of pipe containing the solid compound, dissolving a small portion and then returning to the main stream of the feed-water inlet. This requires a nice adjustment of the stream which passes over the solid compound, so that it shall dissolve enough, but not too much, but it is probably the most satisfactory method of feeding the compound.

In the small installation, the boiler compound has an immense advantage over the precipitation water-softener, for the original cost of the water-softener is greater in proportion to the rated capacity in a small installation than in a large one. In addition to this the precipitation water-softener does not work so satisfactorily on small amounts of water—say from 100 to 250 gal. per hr.—as it does on larger amounts—from about 500 gal. per hr. up.

LOCAL CONDITIONS DECIDE METHOD TO BE USED IN THE CASE OF LARGE INSTALLATIONS

On larger installations, the question of the superiority of one or the other method of treatment depends upon local conditions. Under average conditions, boiler compound will produce better results with water-tube boilers. The author has, just this morning, inspected the turbinizing of a large water-tube boiler at the plant of a large chemical manufacturing concern. This boiler was in excellent condition, there being slightly less than $\frac{3}{8}$ in. of scale in the tubes, and about $\frac{1}{2}$ in. on the plates. The chief engineer of the plant told me that this was the first time in over a year that this boiler had been turbinized, that they had been operated twenty-four hours per day and had been run on an overload averaging at least 25 per cent, and that during the peak of the day's run the overload frequently reached 100 per cent. The water used in these boilers is Lake Michigan water, which carries 7.6 grains per gal. (slightly over 1 lb. per 1,000 gal.) incrusting salts; and it was treated solely with boiler compound. The reason that boiler compounds will produce better results with a water-tube boiler than will the precipitation water-softener is the fact that foaming preventives can be incorporated into the compound, whereas they cannot in the softener, and a very slight over-treatment of the water in a precipitation softener will cause water to be carried over with the steam from a water-tube boiler, especially at times when the boiler is carrying an overload.

For locomotive boilers the same consideration will obtain as with the water-tube boilers, for they are more subject to trouble from foaming and priming than even the stationary water-tube boilers.

BEST METHOD FOR FIRE-TUBE TYPE OF BOILER

On the fire-tube type of boiler, where there is not so great danger of foaming and priming, for average waters (those running over 8 grains per gal. of incrusting salts) the precipitation softener exhibits its best results; and it is usually superior to boiler compounds on the larger installations where it is possible to give it the proper attention. Accurate statistics are not available, but this will probably cover over 50 per cent of the stationary boiler horsepower in this country. For waters which run unusually high in incrusting salts (60 grains per gal. and over) or which run high in sodium

salts, boiler compounds will usually prove superior, as also is the case with waters whose incrusting salts run much lower than the average (less than 8 grains per gal.).

GENERAL SUMMARY

For laundries, textile mills, dyeing plants, manufacturing of chemicals, extracts, etc., the quality of whose products is lowered by the presence of calcium or magnesium salts, the zeolite water-softener is preferable if the raw water is such that the zeolite water-softener can handle it and if the presence of sodium salts in the water has no injurious effect.

If the water for the above industries cannot be handled by a zeolite water-softener, treatment by the precipitation water-softener will usually prove economical and valuable.

For the manufacture of raw-water ice, the precipitation water-softener is the only satisfactory method of treating.

In larger installations, with an average hard water, which shows no tendency to foaming or priming, for fire-tube boilers, the precipitation water-softener produces the best results.

In smaller installations, or with a low hardness, or an extremely high hardness, for fire-tube boilers, properly prescribed compounds are preferable.

For water-tube boilers of any size and for locomotives boiler compounds usually show best results.

Where high amounts of sodium salts predispose the water to foaming and priming, boiler compounds give best results.

In cases of electrolytic corrosion, the use of a zinc-bearing boiler compound will frequently correct the trouble.

From the above conclusions it is apparent that each type of water purification has a fairly well-defined field in which it is unquestionably *best*. The fields, however, where either of two different methods of treatment would give good results are quite frequently met with, and in these cases individual considerations would decide which of the two methods would be better. If the proposed installation be large enough to justify such action, it would be to the best interests of the user of water to obtain the impartial advice of some reputable consulting engineer.

The Calcium Requirement of Man

Prof. H. C. Sherman of Columbia University has reported in the *Journal of Biological Chemistry* (vol. 44, pp. 21-7, 1920) a series of figures on the calcium content of various diets, and found that in 227 supposedly typical American diets, while only one was deficient in protein, 37 were deficient in calcium. If all diets furnishing less than 3,000 calories had been increased to that level—i. e., to furnish 3,000 calories—none would have been deficient in protein, but 7 per cent would still be deficient in calcium. Prof. Sherman, who is acting head of the department of chemistry and is one of the leading authorities on food chemistry, emphasizes the importance of increasing the intake of calcium by adding calcium carbonate or phosphate to the diet, or, better still, by increasing the intake of milk and other foods which are rich in lime. Milk has the advantage of increasing the high-grade proteins and of providing the fat-soluble vitamins.

Legal Notes

BY WELLINGTON GUSTIN

Device Having "U. S." as Most Prominent Feature Not Registrable

The Court of Appeals of the District of Columbia has affirmed the decision of the Commissioner of Patents denying to the United States Rubber Co. registration as a trade-mark for shoes the letters "U. S.," written on a disk, with other less conspicuous wording around the border.

The Patent Office had said that the meaning of "U. S." was too clearly established to permit of registration of any mark having that as the most prominent feature. This was agreed to, the decision being based upon section 5 of the trade-mark act, which denies registration to any mark which "consists of or comprises the flag or coat of arms or other insignia of the United States or any simulation thereof, or of any state or municipality or of any foreign nation."

Negligence in Handling of Acids—Care Required to Prevent Injuries to Others

Negligence in the handling of acid is the question presented in the recent decision of the Supreme Court of Rhode Island in the matter of McHugh against Williams & Payton. The latter were manufacturers, using acid in connection with their business. They had a carboy of sulphuric acid stored on the third floor of the building which they occupied. The acid commenced to leak and a quantity went through the floor, falling upon McHugh, who was working for another manufacturing company on the second floor. Because of the severe burns received McHugh brought an action for negligence to recover damages sustained on account of the negligent handling of acid by the defendants. From a judgment against the company an appeal was had and the Supreme Court has reversed the judgment, granting a new trial to the company.

In the court's opinion it appears that, under the Rhode Island workmen's compensation act, had the employee made claim against his employer for compensation and had been paid such compensation he would be barred from bringing an action for negligence against the third party who was responsible for the injury. But this defense was not available in this case.

It was contended for the injured employee that it was the duty of the defendants to use reasonable precaution in placing these acids and in the care of them so that they might not leak upon persons on the floor beneath. The question was presented: What was the duty of the manufacturing company with respect to the care of handling the acid? The court said that its duty was to handle this acid so that it would not injure innocent parties in any other section of the building; and to accomplish this its duty was to use what would be called ordinary care and diligence for the safety of others.

ORDINARY CARE DEFINED

Ordinary care was stated to be such care as a person of ordinary prudence exercises under the circumstances of the danger to be apprehended. The greater the danger

the higher the degree of care required to constitute ordinary care, the absence of which is negligence. It is a question of degree only. The kind of care is precisely the same. (52 Atlantic, 1090.)

The trial court held for the employee that, for injuries from a latent defect which cannot be discovered, the defendant is never liable, but that defendant was bound to make such an investigation of the flasks of acid as would lead it absolutely to know that all of them were sound and that there was no crack in them that would permit leakage. But the Supreme Court held this view was erroneous, that the defendants were required to use only ordinary care and diligence in making an investigation as to the condition of the soundness of the flasks, and not make such a particular investigation of them as would lead them absolutely to know that they were sound.

The case was reversed on this erroneous ruling of the lower court. To require the defendants to make such investigation of the flasks as absolutely to know their condition would require them to exercise the highest degree of care under the circumstances, or to be insurers of the condition of the flasks, and this degree of care is not required in the case herein, but only ordinary care under the circumstances and conditions.

Secret Processes and Letters Patent—Nature of the Rights Therein Distinguished

The nature of a patent right for a secret process or invention and one's property right to discoveries undisclosed to the public are considered in a novel case in the New York Supreme Court. A judgment creditor sought to force his debtor to answer questions that would reveal the nature of his claimed invention. Under the New York law a debtor may be examined "concerning his property," and therefore the court said that if the subject matter of the debtor's ideas or claimed invention constituted property rights then the debtor must answer the questions propounded to him.

It appears that the debtor had constructed some models of his ideas but he had not obtained a patent thereon; neither had he made an application for patent, nor has he made his ideas public. In deciding the matter Justice Cropsey gave a clear statement of the law.

It was said that an inventor may assign or transfer his rights to his invention, before making application for a patent, but even where that is done the application for the patent must be signed by the inventor. (94 U. S., 225).

NATURE OF A PATENT

The federal Constitution has conferred upon Congress the power to secure, for a limited time, "to authors and inventors exclusive right to their respective writings and discoveries"; and under this clause Congress has laid down the rules and regulations for granting of letters patent. To obtain a patent the inventor must make application to the Commissioner of Patents, and file with him a description, "in such full, clear, concise and exact terms as to enable any person skilled in the art or science to which it appertains . . . to make, construct, compound and use the same." A patent grants for the term of seventeen years the exclusive right "to make, use and vend the invention or discovery." This exclusive right is a legal monopoly, entirely the creature of statute. At common law there is no exclusive privilege. (9 Supreme Ct., 168.)

The inventor always had at common law, as he now has under the statute, the right to preserve the secret

of his inventive genius, and to enjoy the fruits of every legitimate utilization thereof, said the court; but upon permitting his secret to become known, his exclusive rights terminated and his secret became public property. His exclusive right to his invention depended upon his success in guarding his secret.

Now, while a patent confers the right of monopoly and the resulting benefits, it grants to the inventor no right in the conception of his mind, in the secret of his invention that he did not possess before.

TWOFOLD PURPOSE OF PATENT STATUTE

A twofold purpose was said to be accomplished by the statute authorizing the issuance of letters patent. First, it secures to the public forever, after the expiration of the patent, the benefits flowing from the inventor's genius, and, second, it rewards the inventor by giving him, for a limited period, the exclusive privilege of making, using and vending his product. The inventor is rewarded, not for making the discovery, but for disclosing his secret to the public. The disclosure by the inventor is the consideration for the grant of a monopoly by the Government. (30 Cyc., 816.)

In another case, Federal Judge Sanborn said:

"A patent is a contract by which the Government secures to the patentee the exclusive right to vend and use his invention for a few years, in consideration of the fact that he has perfected and described it, and has granted its use to the public forever after." (106 Fed., 693.)

A SECRET PROCESS IS NOT PROPERTY

Therefore, the right possessed under a patent consists in the exclusive privilege or monopoly of making, using and vending the physical product of his invention, and not in the secret hidden in the inventor's mind. When the inventor has made application for patent and has described his invention in "full, clear, concise and exact terms," he has made the required disclosure to the public and is entitled to a patent. This right to patent has been held to be a property right. But before the application is made the right is merely a common-law right to enjoy the fruits of his invention so long as he may be able to keep it secret. Upon discovery being made, the secret inures to the benefit of the public. Therefore, said the court, this right lacks the primary and essentials characteristic of property, which is the capability of being exclusively owned, possessed and used. And before application is made for a patent, the inventor has no property right in the invention which can be subjected to the payment of his debts. But when a patent has been issued, the inventor can be compelled to make an assignment of his property right for the benefit of his creditors.

RIGHT OF INVENTOR TO GUARD AND PRESERVE HIS SECRET IS WELL ESTABLISHED

But it does not follow that an inventor can be compelled to file an application for a patent. The right of the inventor to guard and preserve his secret is as well established as is his right to secure from the Government a monopoly by disclosing his secret, and the inviolability of the common-law right of the inventor to preserve his secret is guarded by federal statute.

Therefore the court held, in the instant case, that the right of an inventor, before he has disclosed his secret, is not property in the general sense requiring the judgment debtor to answer questions revealing the nature of his undisclosed invention.

Motion Pictures in Physical Testing Laboratory

By H. J. FRENCH, MET. E.

In studying the properties of boiler plate at various elevated temperatures, including those reached in boiler operation, crude oil distillation, etc., it became desirable to determine the effect of variations in rate of stress application. The factor considered of greatest interest, the limit of proportionality in tension, is generally determined at room temperatures from measurements of elongation under successive increases in load. This procedure, which probably requires the simplest form of apparatus, has likewise been used at elevated

FIG. 1. COMPLETELY ASSEMBLED APPARATUS

temperatures,¹ but is not sufficiently flexible to allow much variation in rate of application of stress or measurement of strain under continuous loading without materially affecting the accuracy of the results obtained. It is here that the motion picture camera finds its application, makes possible the elimination of a complicated mechanism and permits a permanent photographic record of stress and strain to be obtained under continuously increasing load applied at very different rates. Thus its purpose becomes the rapidly repeated and simultaneous photographing of a number of indicators which are always in motion.

Fig. 1 shows the completely assembled apparatus, in-

¹"Tensile Properties of Boiler Plate at Elevated Temperatures," *Mining and Metallurgy*, No. 158, Section 15, February, 1920. *CHEM. & MET. ENG.*, vol. 22, p. 392 (March 3, 1920).

FIG. 2. SHOWING BELTS AND PULLEYS OPERATING LOAD-INDICATING DISK

FIG. 3. DEFORMATION-MEASURING DIALS

cluding camera, used in determination of the limit of proportionality at room and various elevated temperatures. The load-indicating disk is driven by belts and pulleys, as shown in Fig. 2, from the screw operating the rider on the beam of the testing machine, while the two compensating dials measuring deformation are mounted on frames, shown in Fig. 3, which in turn are attached to the test specimen by two yokes. The dials are turned, however, to face in one direction. This arrangement is used to bring these three instruments into nearly one plane and as close together as possible in order that the largest images possible may be obtained on the film, an enlargement of which is shown in part in Fig. 4. The testing machine and camera are operated independently at any reasonable speeds, so that a wide variation in rate of loading and number of photographs of the dials may be obtained.

The test specimen is placed in a tubular electric-resistance furnace and may be loaded at various tempera-

FIG. 4. SECTION OF FILM, ENLARGED

tures. After completion of the test the film is developed and then projected by means of a simple device which allows as much time as desired for obtaining individual readings from any one exposure. From readings so obtained a stress-strain diagram is plotted in the usual manner and the limit of proportionality is obtained. In this case, however, the strain is half the algebraic sum of the deformations recorded by the two compensating dials.

By this method the effect of rate loading on the tensile properties of firebox boiler plate has been studied.

Synopsis of Recent Chemical & Metallurgical Literature

Illuminating and Heating Gas From Wood Distillation.—The industry of manufacturing illuminating and heating gas from wood distillation has made rapid progress in Switzerland during the last few years. The disadvantages of wood gas (presence of great quantities of acetic acid, which is harmful to the life of the pipings, and of carbon dioxide) have been greatly reduced by the use of an improvement in wood distillation which consists in passing the gas through incandescent charcoal. The consumption of charcoal is from 1 to 3 kg. per 100 kg. of wood or 3 to 6 kg. per 100 cu.m. of gas. Tests have shown that by this improvement the following results are obtained as compared with those for a simple distillation of the wood:

The amount of gas produced from a given quantity of wood is nearly doubled.

The carbon dioxide content is reduced 25 per cent.

The calorific value of the gas is reduced 22 per cent.

The heavy hydrocarbon content is reduced about 66 per cent.

The methane content is reduced 50 per cent.

The hydrogen content is increased 80 per cent.

The tar content is decreased 50 per cent.

The acetic acid content is reduced to a practically negligible quantity. The apparatus and pipings are not deteriorated by these small quantities of acetic acid.

The gas produced is much lighter.

The water content of the tar is greatly reduced, thus improving its selling price.—From *Journal für Gasbeleuchtung*. See *Génie Civil*, Nov. 27, 1920, pp. 439-440.

Brass-Casting Practice.—An important research on "The Influence of Gases on High-Grade Brass" was presented before the fall meeting of the British Institute of Metals by T. G. BAMFORD and W. E. BALLARD. Their theoretical studies were supplemented by pouring experiments in a brass foundry and their conclusions were verified in this manner.

It was judged impossible to discover the exact amount of gas present in solid brass by heating it in a vacuum, because the total amount of contained gas would not be evolved and at the same time a considerable amount of zinc would be volatilized. Specially prepared brass was therefore heated at a uniform rate in a tight tube containing a pure gas and the absorption at different temperatures inferred from the change in pressure. Comparing the curve thus plotted with a blank run with no metal, it was found that CO_2 was apparently not absorbed by brass, CO was absorbed to a slight extent, and H_2 showed a fairly large and regular absorption. Sulphur dioxide was absorbed in large quantities between 300 and 1,020 deg. C., at which temperature absorption ceases and an evolution of gas commences, becoming more rapid up to 1,100 deg. C. A marked chemical reaction takes place, producing heavy scale, accompanied by sulphidation, dezincification and the formation of blowholes. No results were possible with methane due to complex reactions accompanied by carbon deposition.

Experiments were then devised and executed to

measure the rate of reaction between SO_2 and brass, and the results were interpreted to mean that under the small partial pressure of SO_2 existing in any furnace atmosphere this gas could not be absorbed by brass at a correct pouring temperature, but would be actually eliminated from the metal.

This implies that the metal must be hot enough to remain fluid in the mold for a few minutes after pouring, and is one reason why brass cannot be poured at too low a temperature.

Experiments to measure the solubility of H_2 in brass were then undertaken, despite the apparent difficulty. Hydrogen-free brass was finally prepared by melting the metal in an atmosphere of CO_2 , bubbling this gas through the metal for about half an hour, pouring and cooling the metal in a carbon dioxide atmosphere. An ingenious experimental apparatus was then devised for bringing the brass to the desired temperature in a neutral atmosphere, replacing this with an atmosphere

TABLE I. 70:30 BRASS (71.10 PER CENT COPPER)

of hydrogen without involving heavy zinc losses, and the measurement of the weight of the hydrogen absorbed. The notable and important feature of these experiments is that the solubility determinations were made without subjecting the brass to any pressures differing largely from that of one atmosphere. The results are shown in Table I.

Several different investigators agree that H_2 is soluble in Cu at 600 deg. C., with a solubility rapidly increasing with temperature, reaching 0.3 mg. in 100 g. at 920 deg.

TABLE II. BRUNNER MOND ZINC (CAST IN CO_2)

Temperature, Deg. C.	Solubility, Mg. per 100 g.
750	1.3
600	3.5
300	4.8

C. Little information is available on H_2 and Zn, however, so experiments tabulated in Table II were performed.

Evidently 70:30 brass can absorb much more H_2 than can either of its constituents.

Having determined the fact that hydrogen was absorbed in large quantities, it was important to discover how it could be extracted from the metal. This was done by heating weighed samples of brass in a stream of dry carbon dioxide to oxidize any hydrogen in the sample and then collecting and weighing the water formed in the reaction.

It would appear from the results that a large proportion of the hydrogen retained in the brass is easily removed by heating at 600 deg. C. or above. The major portion of the hydrogen absorbed during heating is usually retained on cooling.

Brass can evidently either adsorb large quantities on its surface, or large quantities can actually pass into the metal.

In the former case, clearly, such adsorbed gas could

not be responsible for internal unsoundness, and in the latter case, since the H_2 could diffuse through the metal, it could hardly develop sufficient internal pressure to be responsible for blowholes. Such an argument does not apply in the case of SO_2 , which in connection with an unsuitable pouring temperature might be responsible for unsoundness.

Investigation was therefore carried out on the relationship existing between the casting and pouring temperatures and the qualities of brass casting. Billets were cast in a brass foundry, observing the temperatures of casting and examining the condition of the billets at the end. Furthermore, a special furnace was designed and built with the object of obtaining a positive answer to the question as to whether any particular furnace gas would have a deleterious effect upon the quality of brass castings, provided the metal was poured at the correct temperature.

These practical experiments verified the following theoretical conclusions completely:

1. In ordinary foundry practice, using a coke-fired natural-draft wind furnace, it is impossible to impair seriously the mechanical properties of the casting by overheating.

2. Cooling the metal to within 40 deg. C. of the liquidus will certainly ruin the mechanical properties of high-grade brass which has been melted in ordinary furnace atmospheres, and will probably render the casting porous.

3. In casting tubes a higher temperature is needed than when casting solid ingots, and it is not advisable to cast 70:29:1 tubes below 1,150 deg. C.

4. Exceptionally prolonged periods of heating of the metal in the furnace do not impair the mechanical properties of the resulting casting, but of course are to be deplored for commercial reasons, on account of the consequential high zinc losses.

5. The furnace treatment is not a deciding factor in influencing the quality of the casting, but the pouring temperature is the notable factor.

6. Unsoundness is usually confined to the upper portion of a casting.

Carbide in Quenched and Tempered Steels.—In the thirty-eighth report of the Japanese Iron and Steel Institute SEIZO SAITO determines by means of magnetic and X-ray analysis that it is immaterial whether one says that cementite or carbon is dissolved in iron to form austenite, since both these phrases refer to the same atomic configuration. If free carbon does dissolve in iron when the mass is heated above the transformation it is reprecipitated as cementite. When tempering a quenched steel at about 300 deg. C. cementite is first set free, but owing to the extreme fineness of the particles the greater part readily decomposes. (Eutectoid steel first separates cementite on tempering at 130, and precipitation is complete at 360 deg.) Honda had previously found that the amount of precipitated cementite reaches an asymptotic value at about 400 deg. C.; further heating to 700 not appreciably increasing its quantity; the amount is less than the value before quenching, possibly by a value equal to that which decomposes when extremely finely divided. Coagulated cementite forming a comparatively large grain (pearlite) or massive cementite in hypereutectoid steels does not decompose below A_1 to any extent, but in the latter case free cementite does partly decompose above A_c .

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Ammonia-Soda Process.—In the usual ammonia-soda process the mother liquor obtained by filtering out the sodium bicarbonate contains small proportions of sodium and ammonium bicarbonates and large proportions of sodium and ammonium chlorides. This liquor is treated with lime in the ammonia stills for the recovery of ammonia. Nearly one-half of the original sodium chloride is lost in the calcium chloride brine, so that the process cannot be worked commercially except at places where salt can be very cheaply obtained. According to a modification proposed by TORANOSKE NISHIGAWA of Tokyo, Japan, more sodium chloride is added to the filtrate after the separation of sodium bicarbonate and ammonium chloride is precipitated by cooling to below 5 deg. C. Prior to cooling, sufficient ammonia is added to the liquor to convert the small proportion of bicarbonates into normal carbonates. This ammonia is prepared synthetically from the gas from the scrubbers and carbonators, which is almost pure nitrogen. Either the cyanamide or the Haber process may be used. After filtering off ammonium chloride, the mother liquor (containing ammonium carbonate, sodium chloride and some ammonium chloride) is returned to the absorbers to form ammoniacal brine. (1,359,097; Nov. 16, 1920.)

Phosphoric Acid.—FRANK S. WASHBURN of Rye, N. Y., has improved the process for the production of phosphoric acid from phosphate rock described in his earlier patents—1,047,864, Dec. 17, 1912, and 1,100,639, June 14, 1914. An electric furnace is charged with a mixture of phosphate rock and silica and the necessary amount of carbon is fed in from a hopper in the top of the furnace. Further quantities of phosphate and silica are fed from a bin to a rotary kiln and then pass through a hearth furnace before entering the electric furnace through a side opening. The hot gases and vapors from the electric furnace pass through the hearth furnace and kiln in the opposite direction and thus serve to preheat the charge so that maximum thermal efficiency is obtained. (1,359,211; assigned to the American Cyanamid Co.; Nov. 16, 1920.)

Anhydrous Magnesium Chloride.—Needle crystals of magnesium chloride are partly dehydrated by the use of large volumes of heated air until the melting point of the salt is raised above 250 deg. C. The material is then placed in a retort and a current of dry HCl is passed through while the temperature is slowly raised from 150 to 650 deg. C. The product is 98 to 99 per cent $MgCl_2$. (1,359,652; EDGAR A. ASHCROFT of London, England; Nov. 23, 1920.)

Magnesium.—Metallic magnesium is prepared from anhydrous magnesium chloride, made according to the process described in U.S.P. 1,359,652, by the use of a twin cell electrolytic apparatus. In the primary cell the anodes are of graphite, the cathode is a molten magnesium:lead alloy and the electrolyte consists of fused

anhydrous magnesium chloride. Magnesium:lead alloy from the primary cell forms the anode of the secondary cell and the metallic magnesium which collects at the iron cathodes floats on the surface of the fused MgCl_2 electrolyte and is removed periodically. A current efficiency of 90 to 95 per cent is claimed. The primary cell voltage varies from 4 to 6 volts; that of the secondary cell from 1 to 2.5 volts. The current density is such that the surplus energy maintains the contents of the cells in fusion—that is, at about 750 deg. C. When magnesium alloys are made, only the primary cell is used. The chlorine gas evolved at the primary cell is absorbed in a water emulsion of lightly calcined magnesite, forming magnesium chlorate and magnesium chloride in the molecular proportions of 1:5. The chloride is crystallized, dehydrated and used as electrolyte. The chlorate may be used as such or it may be converted into potassium chlorate and magnesium chloride. (1,359,653 and 1,359,654; EDGAR A. ASHCROFT of London, England; Nov. 23, 1920.)

Magnesium Chloride.—Slaked dolomitic lime is treated simultaneously or successively with an amount of CO_2 equivalent to the calcium in the lime and an amount of SO_2 equivalent to the magnesium content of the lime:

Calcium chloride is then added to convert the magnesium sulphite into magnesium chloride:

The precipitated carbonate and sulphite of calcium are removed by filtration. (1,359,782; EDWIN O. BARSTOW of Midland, Mich., assignor to the Dow Chemical Co.; Nov. 23, 1920.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Recovering Tin and Zinc From Scrap.—Zinc chloride, palmitin and tin are recovered from the scruff from tinning pots. The scruff is crushed to pieces about $\frac{1}{4}$ in. in diameter, agitated in a tank with about one-fifth as much water below 60 deg. F. until the zinc-chloride solution obtained has a specific gravity of 1.3, when it is drawn off and filtered in a filter press. The remaining sludge in the tank contains palmitine, which term includes palmitin and palmitic acid, tin, tin oxide and a small proportion of chloride of zinc and is ground with water to a paste and screened to remove the heavier particles of tin. "Tin soap," which consists of tin oxide and palmitine, and a proportion of the lighter particles of tin are also separated in the screening operation and are then agitated in a vessel when the tin sinks and the supernatant palmitine and tin oxide are filtered to remove water, treated with sufficient hydrochloric acid to dissolve any zinc and tin oxychlorides, filtered, dried and distilled. The distillate contains a mixture of palmitin and oil. (Br. Pat. 151,374. G. H. CLEGG, Cardiff; Dec. 8, 1920.)

Cracking Hydrocarbons.—In decomposing heavy hydrocarbon oils to yield lighter oils by heating them under pressure, the free carbon which is formed is continuously removed. The oil is heated in a furnace-heated vertical still 30, containing a rotary scraper 44 and is kept normally full of oil. Vapors and oil from the still pass up a pipe 50 to a separating chamber 14, from which the oil passes by a pipe 54 to an insulated

vessel 22 in which the oil rises slowly upward and passes through a screen 24. The suspended carbon deposits in the vessel or is retained by the screen. The oil returns to the still by a pipe 26. The vapors may be passed from the chamber 14 by a pipe 56 to a chamber 12 in which the temperature is controlled by passing the oil supply through a greater or less length of the coil 10. The heavy oils condensed in chamber 12 are passed by a pipe 60 into the vessel 22 and the vapors pass to a condenser 64. The oil supply may be pre-

heated by passage through the coil 10 and a coil 16 in chamber 14 and is admitted to the vessel 22 by a pipe 18. The bases of the vessel 22 and the still 30 are fitted with blow-off cocks 70, 74 to remove deposited carbon. The circulation of the oil among the still 30, the separator 14, and the carbon-removing vessel 22 may be assisted by a pump. The pressure within the circuit is maintained between 60 and 120 lb. per sq.in., and the temperature between 370 and 450 deg. C. (Br. Pat. 151,925; not yet accepted; R. D. GEORGE, Boulder, Col.; Dec. 15, 1920.)

Washing Crystals.—Crystals deposited from a solution containing more than one salt are freed from mother liquor in a centrifugal machine, the process being completed by treating the crystals immediately the bulk of the mother liquor has been removed with water in a state of fine subdivision, either as spray or wet steam, so that no dry air can enter the mass until all the mother liquid has been removed. The crystals are preferably taken from the evaporator and treated at the temperature of their formation, the steam being introduced at a temperature suitable to bring about this result. A centrifugal machine which can discharge the crystals without stopping is preferably used. The process is described in connection with freeing crystals of sodium carbonate from a liquid containing common salt. (Br. Pat. 152,041, J. T. WINDRAM, Johannesburg, S. A.; Dec. 15, 1920.)

Dyes.—The products obtained by treating the sodium or ammonium salts of nitrated diphenylamine compounds with an alkaline cyanide in aqueous solution dye wool brown to purple shades. The diphenylamine compounds should yield water-soluble alkaline salts; the examples provided being hexanitrodiphenylamine, tetranitrothiooxydiphenylamine, 2:4-dinitrodiphenylamine-*p*-sulphonic acid and 2:4-dinitrodiphenylamine-*m*-sulphonic acid. (Br. Pat. 151,868, BRITISH DYESTUFFS CORPORATION and J. TURNER, London, and L. G. BADIÉ, Huddersfield; Dec. 15, 1920.)

Fixed Nitrogen Corporation Bill Passes Senate

By a vote of 34 to 29, the bill providing for the creation of the United States Fixed Nitrogen Corporation was passed by the Senate Jan. 14 after it had been extensively amended. The chief responsibilities were vested in the President and the handling of the business end of the organization was lodged in the Secretary of the Treasury. Originally the bill provided for vesting most of the responsibility in the Secretary of War, who also was to be in complete charge of operations.

While the passage of the bill by the Senate is regarded as a victory for those favoring it, there is much doubt whether it will be passed by the House. If the bill can be brought to a vote there, it probably will pass, but under the rules it will be difficult to bring it before the House without having the consent of the majority leaders, and it is doubtful if that can be obtained.

The debate on the bill was particularly acrimonious. Senators Wadsworth, Lenroot, Poindexter and others were accused of filibustering against the measure. Although this charge was denied, it is evident that the opponents of the bill left little unsaid in regard to it. For that matter, however, the proponents of the bill occupied much time with their arguments.

The opposition to the administration of the corporation by the War Department was led by Senator Wadsworth, of New York, chairman of the Committee on Military Affairs. In that connection he said: "I think the Secretary of War should not be burdened with more civil jurisdiction. We have piled him with it in recent years. This bill, as drafted, would make him the responsible head for the carrying on of a great commercial business, the manufacture and sale of fertilizer. Military men are suggested as officers of this commercial corporation. Army officers are not trained business men. Soldiers ought not be assigned to work of this character.

"This enterprise should be put under the Treasury Department and business men. The Treasury Department is the business end of the Government."

The desires of Senator Wadsworth in that connection were adopted finally without objection.

An important amendment embodied in the bill just before it was passed provided that:

"The corporation shall be conducted under the supervision and control of a board of directors consisting of not less than five nor more than seven members, to be appointed by the President, by and with the advice and consent of the Senate."

The provision authorizing appointment of army officers as directors was stricken out. The bill was also amended by denying condemnation power to the corporation.

During the discussion of the bill Senator Smoot charged that the principal purpose behind it was not national defense or the manufacture of fertilizer, but the harnessing of a water power at Government expense for the use of the industries and the utilities in the territory tributary to Muscle Shoals.

Sheffield Scientific School Lecture Course for Graduate Students

The following program of lectures at Sheffield Scientific School, Yale University, by well-known leaders in the chemical world, has been arranged so as to give the graduate students of organic chemistry a broader vision of its application in the industries and the inspiration, which comes by contact with such men, to seek further the truths revealed by research:

1. Prof. R. H. McKee, professor of chemical engineering, Columbia University, New York City.

2. Prof. E. V. McCollum, professor in department of chemical hygiene, Johns Hopkins University, Baltimore, Md.

3. Prof. H. N. Holmes, chairman of department of chemistry, Oberlin College, Oberlin, Ohio.

4. Dr. David Wesson, technical director, Southern Cotton Oil Co., Savannah, Ga.

5. Dr. M. L. Crossley, research director, Calco Chemical Co., Bound Brook, N. J.

6. Dr. P. A. Levene, chemist, Rockefeller Institute for Medical Research, New York City.

The first speaker, Prof. McKee, will deliver two lectures as follows: Jan. 20 at 8:15 p.m., on "Tendencies in Chemical Engineering Education"; Jan. 21 at 9 a.m., on "Plant Problems Falling to a Chemical Engineer."

Stamford Chemical Society Elects Officers

The officers elected to take charge of the affairs of the Stamford, Conn., Chemical Society are: President, G. C. Givens; vice-president, S. D. Shipley; secretary, F. B. Wilson; treasurer, R. H. Stevens; director, E. H. Smith.

At the next regular meeting on Jan. 24, Dr. Allen Rogers of Pratt Institute will give an illustrated lecture on "The Utilization of the Shark."

Fellowships Open at Urbana

Sixteen research graduate assistants are maintained by the Engineering Experiment Station, University of Illinois, some of which are now open, each of which carries a stipend of \$600 plus fees. Appointments are for two years, and require not more than half the time at the problem assigned, the remainder being available for graduate study. Further information may be had from Dean C. R. Richards, Urbana, Ill.

Meeting of the Syracuse Section of the A.C.S.

The Syracuse Section of the American Chemical Society held a very interesting meeting on Jan. 7. Dr. C. G. Derick of the National Aniline & Chemical Co., Buffalo, delivered a talk on "Methods of Attacking a Research Problem."

Western Canada Pulp & Paper Co. Enlarges

The Western Canada Pulp & Paper Co., which recently took over the Rainy River Co.'s plant at Port Mellon, B. C., has reconstructed and enlarged the plant and is adding new machinery. The enlarged plant will have a capacity of forty tons of pulp per day.

Metric System Bill Introduced

A bill providing for the compulsory use of the metric system as the single standard of weights and measures in the United States has been introduced in the Senate by Senator Frelinghuysen, of New Jersey. The bill was introduced at the request of advocates of the metric system. Senator Frelinghuysen explains that the introduction of the bill by him does not necessarily carry with it any support on his part for the measure, but he sees no reason why the measure should not be introduced so that members of Congress might acquaint themselves with its purport.

Ten years after the passage of this bill the weights and measures of the metric system would be the single standard for the sale of goods and for computing transportation charges and wages. In order to accustom the public to the new system, all goods in package form which are required to be marked in terms of weight or measure must use the metric system beginning two years after the passage of the bill. From the second to the tenth year the customary units may be retained in addition to the metric, if desired. After four years, weighing and measuring devices shall be manufactured in accordance with the metric system.

Certain exceptions are noted in section 12 as follows:

Sec. 12. That nothing in this act shall be understood or construed as applying to—

(1) Any contract made before the date at which the provisions of this act take effect;

(2) The construction or use in the arts, manufacture or industry of any specification or drawing, tool, machine or other appliance or implement designed, constructed or graduated in any desired system;

(3) Goods, wares or merchandise intended for sale in any foreign country, but if such goods, wares or merchandise are eventually sold for domestic use or consumption then this clause shall not exempt them from the application of any of the provisions of this act.

New Jersey Chemical Society Holds Its January, 1921, Meeting

At the regular monthly meeting of the New Jersey Chemical Society held in Newark, Monday evening, Jan. 10, further growth of the society was manifested by the election of thirty-one new members, thereby bringing the total membership to 576.

Dr. M. C. Whittaker, vice-president of the U. S. Industrial Alcohol Co., gave a very instructive address on "Chemical Organization and Management." He said that three factors—the plant, the process and organization—had to be considered in dealing with this problem, and that the organization factor was the most important. The necessity of a one-man power supplemented by disciplined and dependable co-ordinating units whose work accrues to the employer's benefit, to the successful development of an organization, was strongly emphasized.

Of the various problems pertaining to the smooth functioning of the units the following heads were considered: Misfits in Organization, Intelligence vs. Brawn, Doers vs. Excusers, Materialists vs. Dreamers. Emphasis was laid upon the need of studying the individual man so as to place him in a position where he could utilize his natural ability in the most efficient manner.

Various types of organizations were described and discussed. Among these were dry rot, which required a surgical operation as a remedy; young organizations, characterized by what Dr. Whittaker called "the administrative double pass," where everybody passes his respon-

sibility on to some one else; the all bosses, with no one to do the work; and the lop-sided organization, where there exist petty jealousies and a lack of proper balance between the technical and practical sides of the work.

Dr. Whittaker said that a true test of a successfully operating organization was when all the units were functioning smoothly, and the individuals were all working in harmony and in such a way that the man at the head could devote his energy to the problems of development instead of spending most of his time keeping the machinery going.

C. O. Chan, B. S., of the China Commercial Co., Ltd., gave a short résumé of the economic and political conditions existing in China. He said that due to lack of transportation and banking facilities large-scale production was impossible. Although there was a great deal of money in China, it was so distributed and disorganized as to prohibit its use in large amounts which are necessary for the development of industry by modern business methods. The political situation was characterized as a mixture of ancient Chinese traditions and a copy of European and American customs.

Three fundamental political tendencies have gradually been developed since the beginning of the Chinese Republic. They are the vigorous reform tendency represented by Dr. Yat-sen, Dr. Wu Ting-fang and the common people; the progressive tendency led by the scholar Liang Chao Chu advocating moderate reform, and the reactionary tendency represented by the Monarchist party. Besides these, there are two other groups representing powerful interests and privileges, the military, or Pei Yang, group and the Communication, or Chiao-tung, group.

The Monarchist party has become insignificant and is on the decline; the leader of the Progressive party, although exerting great influence by his pen, lacks strong executive ability and consequently the party has never been able to stand on its own feet and is dependent upon whatever other party is in power. The result is that the Military and Communication groups control the situation in northern China, where they are the strongest, and the common people in the southern provinces, where they predominate.

Both the economic and the political situations were depicted so as to give the American manufacturer an idea of the problems which confront him in doing business with the Orient. China, with its 400,000,000 population, represents a tremendous potential buying power and is a great market for manufactured chemicals. In turn she is rich in raw materials such as vegetable oils, camphor, coal, copper, gold, iron ore, antimony and tungsten. Mr. Chan expressed the hope that the United States might grasp this great opportunity to develop a chemical trade which would be of such immense benefit to both parties.

C.W.S. Service School Opens

The Service School of the Chemical Warfare Service at Edgewood Arsenal opened on Jan. 10. The purpose of the school is to develop officers for the command of Chemical Warfare Service troops in the field and to act on the staff of division, corps and army commanders.

In addition to instructing these officers in the specific military problems arising in connection with the use of gas, the men will be schooled in the fundamental chemical problems involved and the chemical properties of the various gases.

The Crocker-McElwain Plan to Help Employees

The Crocker-McElwain Co. and the Chemical Manufacturing Paper Co. have recently announced a plan for the relief of the hazard of unemployment so far as their employees of more than five years service are concerned. Their idea is to place any employee of more than five years service on the salary list. At such times as the mills may be closed the employee will receive salary, and in turn he obligates himself to do other work about the mill than his ordinary position would call for. The nature of this work is to be agreed upon by the employee and his immediate superior. When the mill is operating the workman will receive either salary or the regular wage scale, depending on which amounts to the larger sum per week. This contract may be terminated by either party on giving four weeks notice.

Evaporation Plant to Be Erected at Soda Lake

The Sodium Mining & Products Co. will erect a new evaporation plant at Soda Lake, near Seventy-Mile House, on the old Cariboo stage road. The company has appealed to the Provincial Government, which owns and operates the Pacific Great Eastern Ry., for a spur-line to the plant. Soda Lake is situated 3,700 ft. above sea level, has an area of 100 acres and a sodium carbonate content of 6 per cent; but this, of course, must vary with the seasons of the year. There are a number of smaller lakes in the vicinity that contain about the same amount of sodium carbonate. In 1918 a small evaporating plant, capable of producing two to three tons of crystals daily, was erected.

Book Reviews

PRIESTLY IN AMERICA. 1794-1804. By *Edgar F. Smith*. Philadelphia: P. Blackiston's Son & Co. 1920. 12mo. pp. 173.

In this little book Dr. Smith has achieved a work of rare literary merit. We knew already that Priestly was an English Unitarian minister, that he discovered oxygen, that for the faith that was in him he was mobbed and persecuted so that he fled to America; that to the end of his days he held to the phlogiston theory, and that he died and was buried at Northumberland, Pa.

Then, when we have read the book through, we feel as though we had at least a bowing acquaintance with the old gentleman, who was sixty-one years old when he came here and seventy-one when he died. We get also a sense of his importance as an international character. He lived in very interesting days, at a time when men thought seriously. He was a man of great influence in England, as is shown by a contemporary caricature on the walls of the Chemists' Club which depicts him as aiding in the service of a troublesome feast for King George IV. We get a sense of his importance as a person when we read the addresses presented to him on his arrival in New York, and again on his advent in Philadelphia. We learn of his scholarship and of his familiarity with and practice of the graces of life, by reading his replies. Intense democrat that he was, he remained to the end of his days a person of quality and distinction. He was never commonplace or vulgar.

He began with a pleasant acquaintance with John Adams, but he had no patience with his administration as President, whereas his admiration for Thomas Jefferson and his hearty friendship with him was of lifelong endurance.

It does not appear that he ever left the State of Pennsylvania after he settled down there and during the years of his life in this country he made but four visits to Phila-

delphia. He declined a professorship in chemistry there. He was maliciously attacked by persons of the same habit of mind as those who had persecuted him in England, but it did not worry him. He was always ambitious to see a college started at Northumberland, where he was content to live. A Mr. Bakewell met him in 1795, and found him "a man rather below the middle size, straight and plain, wearing his own hair; and in his countenance, though you might discern the philosopher, yet it beamed with so much simplicity and freedom as made him very easy of access." Another said of him: "The doctor enjoys a game at whist; and although he never hazards a farthing, is highly diverted with playing good cards, but never ruffled by bad ones."

Very gently Dr. Smith leads us to the Northumberland home when his youngest son Harry, who lived with him and was clearing 300 acres of land, went the way of all flesh. It was among his greatest delights merely to be with this eighteen-year-old boy. No attempt is made to lay bare the old man's heart before us. Indeed, little is said, but that little is very subtle, and it carries us into sincere sympathy with him.

Sir Oliver Lodge has said of Priestly that "his experiments were admirable, but his perceptions of their theoretical relations were entirely inadequate and, as we think now, quite erroneous. . . . In theory he had no instinct for guessing right . . . he may also be said to have had a predilection for the wrong end." This is borne upon us as we read of his chemical activities. There is no doubt in his perseverance in what he held to be right. All his life he held to the phlogiston theory and fought for it. It guided his experiments and led him constantly astray. It effectively spoiled most of his writings on chemistry. Indeed phlogiston seemed to be no less than an obsession with him. It had this value, however, that his championship of the cause brought out such forceful and competent opposition from his fellow chemists in America that it requires no stretch of the imagination to say that the ghost of phlogiston was finally and effectively laid for all time by James Woodhouse and his colleagues.

Much of his attention was given to the preparation of his Church History and his Notes on the Scriptures, which, Dr. Smith says, contain an immense fund of worth-while information and knowledge. The infirmities of age weakened his body, but left his mind clear and vigorous until, in the very act of correcting proof of his Church History, he quietly breathed his last on Feb. 6, 1804.

The book is a rare tribute to a great chemist and one of the leaders of the thought of his day. And it is another token of Dr. Smith's rare gift in literary art. We commend it heartily to our readers.

ELLWOOD HENDRICK.

* * *

"THE MAKING, SHAPING, AND TREATING OF STEEL." By *J. M. Camp* and *C. B. Francis*. Second Edition. Published by the Carnegie Steel Co., Pittsburgh, Pa.* Price \$5, cash with order.

This excellent book is unique in its scope, its accuracy, and its lucidity. Those who work with rolled and semi-finished steel products or buy or sell them in quantity, who by curiosity or ambition attempt to learn something about the industry, may rely upon it to give them the maximum amount of information which can be conveyed without entering the realm of the specialist and employing his oft-unintelligible language.

Heretofore the literature (other than that contained in current periodicals) might be classed in three groups. First is a number of elementary books, written in simple language but unfortunately descriptive of a localized industry or a particular branch of the steel business—in other words, either provincial or specialized—and nearly always out of date and out of print. Next is a number of brief texts designed to give college students an outline view of iron and steel—covering more recent practice, but ordinarily assuming a familiarity with elementary chemistry

*Obtainable by non-employees by addressing the Bureau of Instruction, Carnegie Steel Co., direct. Not sold by or through book stores or dealers.

and physics on the part of the reader. Finally there is a certain small group of really excellent books treating some phase of the industry in an exhaustive manner—books of reference and instruction for the engineer in the industry, and requiring advanced knowledge of its technology on the part of the readers. In this group Harbord and Hall's volumes are the only ones in English which attempt to cover the whole field. Unfortunately these are rather expensive, and are largely occupied by British and Continental practice.

Having these conditions in mind, it is not surprising that the non-technical student found much to discourage him in his search for information, and the expert was hard put to suggest books which were not specialized and yet descriptive of modern operations. This new volume by Messrs. Camp and Francis will supply this need and thus fill the great gap. It is not too much to think that it will also become very popular in engineering colleges offering courses in metallurgy. Doubtless numerous engineers and foremen will find it of considerable service in giving notes on many milling operations not ordinarily described even in the most pretentious works, and in providing clear outlines of related phases of their industry.

It should be easily adopted as a text-book since the volume in fact is "the outcome of several years' experience in attempting to teach the metallurgy of steel to salesmen and other non-technical employees." A passage describing an operation which later turned out to be but hazily comprehended could then be recast into more intelligible language. Many pages bear marks of such painstaking revision—notably in the descriptions of the chemistry of the iron- and steel-making processes. While an intelligent reader can easily grasp the chemistry involving the combustion of coke to CO and CO₂, a clear comprehension of the reversible reactions which occur whenever the C:CO:CO₂ equilibrium is disturbed is not so easy, nor is it apparent at first sight how ores can be reduced, iron carburized and even reoxidized by the same two gases. Lacking any analogous phenomena in everyday life, the student will have extreme difficulty in understanding the reactions between slag and metal in an electric or open-hearth furnace—in fact one could venture the assertion that there are few operators or even advanced investigators who have a workable familiarity with the balanced reactions occurring in steel-making processes.

Naturally the treatment of these matters cannot be rigorous and it is a difficult matter to balance lucidity against chance of misinterpretation or minor inaccuracies, but the reviewer has nothing but praise for the result. He can testify to the great pedagogical value of the conception of iron as the oxygen carrier in the purification stages, even though it is debatable whether the oxide actually exists as a definite and separate entity, and even though all oxides appear to be nearly if not quite insoluble in molten and solid iron.

A good discussion of sulphur in the open-hearth is given on p. 236, especially the gain in sulphur from impure fuel. In this connection, one important limitation to the book should be noted—and would probably be instinctively taken by the expert, and that is that the practice described is Steel Corporation practice. While its plants are numerous and its operations tremendous, there are certain very excellent and useful metallurgical methods in daily operation elsewhere which are not practiced by that corporation. It is consequently a record of contemporary practice in the corporation (especially the Carnegie Steel Co.) and when the authors say (p. 181) that "the removal of sulphur in the mixer at all times is so small as to be of minor importance" the sophisticated reader will immediately visualize low-manganese pig iron from the corporation's blast furnaces, and perhaps at the same instant remember the excellent sulphur elimination between blast-furnace and open-hearth described last year by Wheaton of the Bethlehem Steel Co. Hence also the failure to mention the excellent acid open-hearth process, and various other processes in constant use here and elsewhere—puddling, basic bessemer, cementation, and crucible melting. Doubtless for the same reason forging and heat-treating practice

is confined to a short chapter (pp. 508-515), while steel and iron foundry practice and the production of malleable iron are not mentioned.

Is it possible to assume, conversely, that the scant mention given to heat control is due to a widespread disuse of pyrometers in Steel Corporation plants?

On the other hand, perhaps the fifty pages given to the electric furnace and its operation are due to the necessity of introducing the reader to the elementary electrical facts, and for the benefit of their salesmen selling specialties such as highly refined, multiplex, and alloy steels, rather than an appraisal of the relative importance of the process from a tonnage basis, either present or prospective.

These deficiencies in scope are compensated by good discussions on many lines. First there is a series of chapters containing very clear outlines of elementary physics and chemistry, refractories, ores, fluxes and slags. Especially notable is the chapter on fuels for its full discussion of the use of pulverized fuel in open-hearth furnaces, the authors concluding a very favorable appraisal with the suggestion that while its use was "still experimental," powdered fuel gives promise to replace gas in the steel plant. A description of the installations at Sharon, Clairton and Homestead works is included.

Perusal of the chapters on the constitution, heat-treatment and composition of steel at the end of the book should do much to dispel the idea that metallography is a highly complex and difficult subject largely of academic interest. Praise is also due the 200 pages of Part II on the shaping of steel. They contain the most comprehensive description of all modern rolling mill operations known to the reviewer. Many topics are covered not to be expected in elementary books, notably roll design for rails, the shaping of rail joints, rolling of tires and car wheels, inspection of finished material for defects, and the scheduling of orders.

The book itself is bound in limp leather, and can be carried around in one's pocket despite its 600-odd pages. Unfortunately the thin paper does not reproduce half-tones well—in fact, the authors have been too sparing in the use of line drawings to illustrate the early portions of their book covering furnace design and practice. Their descriptions are quite full, and in fact the text is a veritable glossary of terms; but these descriptions would be much enhanced by appropriate sketches. The second half of the book does not suffer in this respect.

From an instructional standpoint, the worst fault in the book results from its avowed aim: to describe things as the authors found them and why they are so, rather than to discuss what they should be. It might be argued that in educating a steel salesman, it would not be well to tell him that steel might be made better than it is today. The present reviewer apprehends more harm than advantage in half-truths, and directs his greatest criticism at the resulting sentiment—sometimes definitely stated—that we are at the crest of excellence. Thus the statement on p. 130 that the "blast-furnace plant is just approaching the uniformity of perfection" is bad news for the blast-furnace man, condemning him to a lifetime of merely doing what has been done before! Again "the old-time method of charging by hand having been entirely superseded by automatic charging" is somewhat overoptimistic, since hand-fired furnaces of the Shoenberger works may be seen when standing at a window in the Carnegie Building. A strong plea is made in the book against the "ridiculous" insistence upon low limits for sulphur and phosphorus, since "it is becoming increasingly difficult to keep the sulphur content below 0.04 per cent," and when the evidence (Unger's tests probably, made by adding sulphur and phosphorus when pouring an ingot) "points so strongly to 0.10 per cent as a limit that may be made to serve as well, for many purposes, at least."

Some things get to be accepted as facts by the majority of men if they are repeated often enough. It would be unfortunate if young engineers, and doubly unfortunate to the Steel Corporation if its staff were in this way to acquire the idea that further progress in steel making is not to be expected, and that 0.10 per cent sulphur and phosphorus are to be accepted without suspicion.

E. E. THUM.

Personal

Dr. C. L. ALSBERG, retiring president of the Washington Academy of Sciences, will deliver his presidential address on "The Relation of Chemical Structure to Physiological Action" before the joint meeting of the Washington Academy and the Chemical Society of Washington on Thursday, Jan. 20.

Dr. L. H. BAEKELAND is on a business trip to Denver, San Francisco and other Western cities.

KENNETH E. BAIRD, formerly chemist at the Pittsburgh byproduct coke plant of the Jones & Laughlin Steel Co., Pittsburgh, Pa., is now chief chemist of the Donner Union Coke Corporation, Buffalo, N. Y.

J. H. BECQUE resigned his position as assistant superintendent of the U. S. Gypsum Co., Washington County, Virginia, Dec. 1, 1920, to accept a commission in the Chemical Warfare Service, Edgewood Arsenal, Edgewood, Md.

HENRY W. BLAKE, senior editor of the *Electric Railway Journal*, was tendered a dinner by his associates in the McGraw-Hill Co. on Jan. 6 in celebration of Mr. Blake's completion of thirty years of editorial work on this magazine. Mr. Blake graduated as civil engineer at Yale University in 1886 and as electrical engineer at the Massachusetts Institute of Technology in 1888, and consequently brought to his editorial work a degree of technical knowledge unusual in those days.

F. E. COOMBS, consulting engineer, San Francisco, is doing supervisory work for the Asti Grape Products Co., which is installing a grape-sirup manufacturing plant at its winery in Asti, Cal.

LOUIS P. DESTRIKATS, of Trenton, N. J., has resigned as general manager of the Ajax Rubber Co., which operates a large plant in Trenton, N. J. The position is now being filled by A. J. McMann, of Detroit, who has been connected with the company for some time. He formerly was affiliated with the United States Tire Co. Mr. Destriats retains his connection as vice-president and director of the company.

J. A. HYNES, of the U. S. Custom House, spoke before the Chicago Chemists' Club recently on "Some Problems of the Customs Chemist."

ALVA N. JAMES, of Evanston, Ill., has just returned from an extensive trip to the Chilean nitrate fields and copper properties.

WALTER L. JORDAN, formerly chemical engineer of the Celite Products Co., has opened an office in New York City as a consulting chemical engineer and is now carrying on work on filtration.

DAYTON C. MILLER, of the Case School of Applied Science, spoke before the Detroit Engineering Society Jan. 7, on "Photographing the Flash From Large Guns and Projectiles."

STEPHEN SCHWARTZ, formerly of the Empire Refineries, is now in charge of the engineering and construction department of the Indiana Oil Refining Co., Columbus, Ind., which concern will erect a refinery complete with lubricating oil department.

PAUL C. SKINNER, general manager of the General Chemical Co.'s plant, Denver, Col., is making an extended business trip to New York City and the East.

H. G. THIELE is superintendent of the Borosolvay potash plant of the Solvay Process Co. at Borosolvay, Cal.

R. C. TOLMAN, director of the Fixed Nitrogen Laboratories, War Department, addressed the Chemical Society of Washington, on Jan. 13, on the subject, "The Third Law of Thermodynamics."

HAROLD VANDOREN, formerly with the Grasselli Chemical Co., has accepted a position as research chemist with the Koppers Co., Pittsburgh, Pa.

Current Market Reports

The Chemical and Allied Industrial Markets

New York, Jan. 17, 1921.

Improved inquiries and orders from miscellaneous sources resulted in a more active state of business in the chemical market. For the first time in many weeks trade sentiment is cheerful and it is believed that the continued strength among some of the leading chemicals will do a great deal to stimulate confidence in the general market.

Buyers are experiencing great difficulty in placing orders on *soda ash* and *caustic soda*, owing to the pronounced scarcity of offerings and the advancing tendency in prices. At the close of the week light ash was stronger than it has been in the past six months and it was exceptionally hard to find a resale lot of any sizable dimension. Those affiliated with the resale distributors of soda ash had to pass up business in several instances and it is known that orders were placed with producers at \$2.20 per 100 lb. f.o.b. works flat. Export parcels in the open market were quoted as high as 2½c. per lb., although no sales were recorded as far as could be learned above \$2.20. As was expected, the advance in soda ash was directly reflected on the market for caustic soda. Sales for the latter chemical have been made as high as 4c. per lb. This is the highest price recorded since early November. Some large sellers of caustic soda stated that there is only enough resale material available to cover wants for a short time, and that unless producers reduce the price of contracts, they will be compelled to rely upon first hands to cover their requirements.

Spot *bichromate of soda* was quoted firm with sellers asking 9¼@9½c. per lb. for standard material. Dealers stated that only a few small lots could be purchased around the inside figures. A little better inquiry seems to be developing for this material and it looked as though any real buying would strengthen prices. Sellers are not inclined to accept February shipment orders except at about 1c. per lb. premium over spot prices. Sales of foreign *muriate of potash* were reported at \$75 per ton, basis 80 per cent, delivered. Both foreign and domestic *muriate* appear to be on a parity at the present time. Quotations ranged from \$75 to \$80 per ton, according to seller. Some interests assert that a keener competition is developing among the sellers of this chemical, although prices have not changed since the first of the year. Resale lots of *bichromate of potash* were on the market at 16@17c. per lb., spot New York. In some quarters it was intimated that a firm offer of 15c. per lb. would probably be accepted for moderate quantities. Inquiry for this chemical has not been active of late and second-hand competition has resulted in the lowering of the spot quotations. While in some quarters 17c. per lb. for *prussiate of soda* was reported acceptable for limited quantities, in others the market was quoted at 17½c. It is possible that small isolated lots can be purchased a shade under these figures, but the general tone was reported slightly firm with a fair amount of small lot business passing.

Off lots of *oxalic acid* were on the market at 80c. per lb. Sellers' views covered the same wide range lately recorded and some producers are asking 25c. per lb. for material ex-store. The general feeling is firm and some interests assert that actual supplies are relatively small. Reports from some quarters on the export situation of *alcohol* are becoming more optimistic and not only is there a greater number of scattered inquiries, but shipments to some ports are increasing in volume. The domestic demand is confined to small lots on the basis of \$5@\$5.50 per gal. Producers quoted *denatured alcohol* at 68@77c. per gal., depending on formula. The demand is of small volume and some holders are said to be shading where business was possible. Trading in *wood alcohol* remained quiet, although a better inquiry was recently noted. Prices ranged from \$1.30 to

\$1.60 per gal., depending on grade. The general aspect of the *glycerine* market was stronger and trading reflected more activity. A fair volume of the c.p. grade moved into consuming channels on the basis of 20c. per lb. in drums and 22c. in tins.

COAL-TAR MARKET

General conditions seemed to have improved somewhat during the last week in some of the markets that coal-tar products are more or less dependent on. From both local and foreign quarters inquiries have been increasing and many are of the opinion that these inquiries mean real business in the very near future.

Crude producers are candid in stating that there is nothing in the line of large lot business, but small orders are coming in more frequently. Prices are holding steady with prospects of a future demand that will further stabilize the market.

Few inquiries were reported for *dinitrobenzene* and the market continued dull. Supplies were abundant, but outside of occasional small lot offerings at reduced prices, first-hand quotations were holding fairly steady. Spot material ranged from 25c. to 30c. per lb., depending on quantity and sellers. The only activity on *dinitrochlorbenzene* is occasional small lot sales. There were few buyers and these were interested in small quantities only. Prices, however, were held steady at 27@30c. per lb. The market in *para-dichlorbenzene* reflected a firm tendency with supplies quoted in car lots at 10c. per lb., and ranging up to 14c. per lb. for lesser quantities. A steady improvement in the demand is looked for, now that conditions in the textile centers are clearing.

Consumers showed little interest in the market on *para-nitraniline*. Producers reported regular supplies available on spot. Prices ranged from 93c. to \$1 per lb. Very little *paraphenylenediamine* is being moved at present on account of most of the large fur dyers being closed. Stocks are not pressing, however, and prices are fairly well held by producers. The average price is \$2.20 per lb., with some variation noted at both higher and lower levels. Second hands are offering *naphthalene flakes*, 79-81 m.p., American make, at 8c. per lb. spot. Producers are quoting contract and future delivery on the basis of 9c. per lb. Trading in *beta naphthol* continued along quiet lines. Producers are holding steady to the present quotations of 45@50c. per lb. Offerings in second hands are still hovering around the market at much lower prices. Factors reported a regular supply of *monochlorbenzene* on the basis of 14c. per lb. in carload lots and while sales are of a light routine nature as yet, the conditions of the consuming end are much brighter for an increased demand.

RUBBER MARKET

Little variation was noted in crude rubber prices throughout the week. Spot *ribbed smoked* sheets were offered quite freely at 20c. per lb., but as far as could be ascertained no business was transacted at this level. Sellers of January are also asking 20c. per lb. Futures remained nominally unchanged with sellers scarce and a fair amount of inquiries received. January-March closed at 21c., April-June at 22½c., and July-December at 25½@26c. One factor reported a small lot sale for April-June at 22c.

NAVAL STORES

There is a firm belief in the trade that buying interest in the near future will increase and prices were advanced by leading interests. A boost of 6c. per gal. on *turpentine* was noted during the week which is now quoted at 75c. per gal. *Rosin*, however, while firmer, remained quoted at former levels. Trading during the week in general showed a moderate increase in small lot business. The Savannah market has not been subject to any change and remained stagnant with no sales reported in either turpentine or rosins.

CORRECTION

In our issue of Jan. 5 we published a table on sodium compounds for 1918-1919 in which we erroneously transposed figures. The following is a correct table of the vari-

ous important sodium compounds produced during 1918-1919:

	1918 Short Tons	1919 Short Tons
Sodium Acetate.....	2,622	2,426
Sodium Bicarbonate.....	118,535	134,962

The Baltimore Market

Baltimore, Md., Jan. 11, 1921.

The expected improvement in the market on fertilizer materials has not yet materialized. Purchases continued to be made on a "hand-to-mouth" basis, and trading is generally in small parcels. Heavy liquidation of stocks held by manufacturers is not to be noted. In fact most of the local fertilizer factories have been closed down since the first of the year and it is thought that normal operations will not be resumed for at least a few weeks. Merchants and speculators, however, are forced by necessity to place some of their materials on the market. These forced sales are being made at prices under nominal quotations.

Fertilizer salesmen are reporting but indifferent success in their campaign for spring business. In certain sections the farmers' organizations have entered into agreements to delay purchasing until fertilizer prices are lowered or prices on farm products are increased.

Acid Phosphate—Acid phosphate can be purchased at \$16 per ton, basis 16 per cent bulk, run of pile. The nominal quotation, however, is about fifty cents per ton above this figure. Raw rock is said to be moving from the mines more rapidly than was the case a few months ago.

Nitrate of Soda—Importers' quotations on this commodity are nominal at \$2.85 per 100 lb. ex-vessel Atlantic ports. Resale lots, however, can be obtained at \$2.75.

Sulphate of Ammonia—Resale lots of sulphate are now offered at \$3.75 per 100 lb., which marks a decline of 25c. since last report. This quotation governs on bagged material in carload lots.

Potash—There are rather heavy stocks of foreign potash in local warehouses at present. It is believed, however, that a surplus does not exist as deliveries from now on will be light. It is also reported that many of the manufacturers have not covered their requirements. The market is quoted nominal; muriate, \$1.70 per unit; kainit and manure salts, \$1.50 per unit. All ex-vessel Atlantic ports. Nebraska potash can be had at a slight premium over the foreign goods.

Fish Scrap—Very little fish scrap has moved since last report. The nominal market has declined 25c. per unit, being now quoted at \$3.75 and 10c. delivered Baltimore in buyers' bags. There are available stocks at the fish factories. Ground scrap sold this week at \$4 and 10c. Baltimore. Prime A menhaden fish oil can be had at 30c. per gal. in tierces delivered Baltimore.

The Iron and Steel Market

Pittsburgh, Pa., Jan. 14, 1921.

Demand in the open market for steel products has not visibly increased. On the whole, demand against old contracts is tending to decrease. With the independents there have been some reinstatements of business, or "releases" in connection with shipping orders previously suspended, the releases being prompted by the revision of contract prices recently down to the Steel Corporation or Industrial Board level, but these hardly make up for the completion from time to time of old orders. With the Steel Corporation, there are still full shipments against contracts on books, but it is apparent that the corporation's customers are not consuming steel in all cases altogether as fast as steel is being received, and an early increase in the rate of consumption will be requisite to forestall a decrease in the Steel Corporation's rate of production and shipments.

Such an increase is not to be expected within the next few weeks. The predictions made in December, that there would be a distinct increase in steel demand immediately after the first of the new year, were probably made from habit. There are many precedents for the making of such a

prediction in December, but there are no precedents for steel demand to increase in January. March or April, and September or October, are the established times for the steel market to broaden. At present, the more sanguine predict a decided improvement in demand before the end of March. Others doubt whether there will be any material improvement before late in the year, if in this year at all.

It is a new situation, or at least a new one for the present generation. The country is not, apparently, suffering from over-expansion in material development, in railroads, office and hotel buildings and dwelling houses. It does not seem to be overstocked with goods, except perhaps in some goods upon which wholesalers or retailers refuse to take the necessary loss, and of course excepting copper, which stands in altogether unique position and must not be used as a basis for generalizing. There is no very serious credit strain, as testified by the smallness of business failures. In other periods of depression and readjustment a decline in prices was essential, but the operation was distinctly subsidiary. Now the principal thing is a great readjustment in values of all commodities and in wage rates and compensation for personal service of various descriptions. It is known what needs to be done, but from lack of precedent it is difficult to estimate the length of time that will be required. The time may prove much shorter than many now estimate, for it is largely a matter of men changing their minds. Experience is still fresh as to how rapidly men can do that in one direction. Why not rapidly in the other?

STEEL CORPORATION TONNAGE

The Steel Corporation's unfilled obligations decreased by 873,359 tons during December. The first decrease was in August, and the decreases have steadily grown larger. There were fair bookings in December, however, for while the decrease in unfilled obligations represented 64 per cent of capacity for the month the shipments may be estimated at about 94 per cent, production being at about 92 per cent, while there was a large movement of tubular goods accumulated, in addition to the current output. Thus the net bookings must have been about 30 per cent, total bookings being in excess of this, in offset of cancellations, of which there certainly were some. The independents, although their order books were almost bare, had light bookings. There is no trend, as was expected by some, for buyers to leave the corporation and patronize independents, while on the other hand there are some instances of buyers, formerly customers of independents, now seeking to obtain a place as Steel Corporation customers.

PRICES

At various times from the middle of November to the end of December the independent market on the different steel products receded to the Steel Corporation or Industrial Board level. The markets are now steady at those prices. There is occasional shading in some commodities by independents, but this shading is distinctly exceptional. The majority of independents are firm in their price views, while the Steel Corporation, with well-filled order books, has no occasion to give the subject a thought.

It is a fair statement that the independents do not cut prices because there is no sufficiently attractive business in sight. Some independents might cut the price on a commodity to secure one fair-sized order, but in general the attitude is that price cutting would not pay. As between operating at 20 to 50 per cent, which is the prevailing range with plants that are not closed entirely, at present prices, and operating at 80 to 100 per cent at prices quite a number of dollars a ton below the present level, the choice would no doubt be instant. When such an operation becomes a possibility the whole price structure in the steel market will be recast if necessary to attain the end.

Steel ingot production in December was at the rate of about 21,000,000 tons a year by the Steel Corporation and at about 10,000,000 tons a year by the independents, or 31,000,000 tons altogether. Independent operations decreased rather steadily during December, but the rate now is about the same as that at the end of December, say 7,000,000 or 8,000,000 tons, while the Steel Corporation's rate remains at about 21,000,000 tons.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

EL SEGUNDO—The General Chemical Co. is building a four-unit contract acid plant. This plant will go in operation some time soon.

Idaho

KELLOGG—The Bunker Hill and Sullivan Mining & Concentrating Co. plans to construct an electrolytic zinc refinery. Estimated cost, \$1,000,000.

Illinois

KENNEY—The Kenney Community High School has awarded the contract for the construction of a 2-story, 104x106-ft. high school, to C. J. Newlin, Normal. Estimated cost, \$84,000.

MARION—The Bd. of Local Impvts. will receive bids about March 15 for building sewerage system and sewage disposal plant. Estimated cost, \$164,000. P. B. Wilson, city engr.

Iowa

PLEASANT PRAIRIE — Bd. Educ., Prairie (Fairport P. O.) is having plans prepared for the construction of a 2-story, 87x116-ft. consolidated school. A chemical laboratory will be installed in same. Estimated cost, \$125,000. Notcott, Donnan & Notcott Co., 516 Black Bldg., Waterloo, archts.

Kansas

WICHITA—The Concrete Products Co., Caldwell Murdock Bldg., plans to construct a 2-story, 150x210-ft. cement plant and warehouse on Rock Island Ave. and 13th St. Estimated cost, \$50,000. Archt. and engr. not selected.

Kentucky

CYNTHIANA—The city is having plans prepared for the construction and equipment of a filtration plant. Estimated cost, \$25,000. J. T. Gillig, engr.

Louisiana

NEW ORLEANS — The Natl. Brewing Co., c/o C. A. Wagner, pres., 2600 Gravier St., has awarded the contract for converting its brewery on Dorgenois and Gravier Sts., into an alcohol manufacturing plant, and constructing a 1-story, 30x75-ft. fermenter building and 4-story, 30x54x75-ft. distillery building. Estimated cost, \$140,000.

Massachusetts

EVERETT—J. Briggs & Co., Inc., manufacturer of paint, 45 Purchase St., Boston, is having plans prepared for the construction of a factory on Paris St., here. Estimated cost, \$25,000.

WOBURN—F. C. Parker & Son, Inc., plans to rebuild tannery which was recently destroyed by fire. Loss \$200,000.

Michigan

DETROIT—Park, Davis & Co., Atwater St. and McDougall Ave., plans to build a 4-story, 100x200-ft. drug factory. Above project is first unit of plant expansion to cost approximately \$4,000,000. Smith, Hinchman & Grylls, 710 Washington Arcade, archts.

TRAVERSE CITY—The Traverse City General Hospital is having plans prepared for the construction of a 3-story, 50x300-ft. hospital. Laboratory equipment will be installed in same. Malcolmson, Higginbotham & Palmer, 405 Moffat Bldg., Detroit, archts.

Minnesota

EVELETH—The city plans to build disposal plant, septic tank and sewer extensions. Estimated cost, \$500,000.

LITTLE FALLS—The Hennepin Paper Co., c/o C. E. Sager, Secy., 1128 Plymouth Rd., Minneapolis, plans to construct a sulphide paper factory here. Estimated cost, \$500,000. Engineer not announced.

Missouri

CLAYTON—City will receive bids about April 1 for building sewers in sewer District 1, 2 and 3. A 50,000-gal. concrete septic tank will be installed in each. Noted Oct. 13.

KANSAS CITY—The C. & C. Developing Co., 705 Ridge Arcade, is building a refinery at 13th and Winchester Sts. This plant will increase its capacity to 1,500 bbl. per day within the next year.

New Jersey

PRINCETON—Boro. plans to construct a sewage disposal plant. Estimated cost, \$30,000. C. P. Browne, mayor.

North Dakota

UNDERWOOD—The Bd. Educ. is having plans prepared for the construction of a 3-story, 80x120-ft. consolidated school. A chemical laboratory will be installed in same. Estimated cost, \$100,000. W. D. Gillespie, Fargo, archt.

Ohio

AKRON—University of Akron, College of Engineering, plans to construct new building to include an engineering laboratory. Estimated cost, \$100,000.

BUCKEYE LAKE—State Bd. Pub. Wks., Capitol, Columbus, and Licking Co. plan to construct a sewage disposal plant, here. Estimated cost, \$75,000. Kenmor & Whitlock, State House, engr.

FRANKLIN—The Bd. Educ. will open bids about March 1 for construction of a 3-story high and grade school. A chemical laboratory will be installed in same. Estimated cost, \$170,000. G. H. Girke, supt. of schools.

WAUSEON — Bd. of Trustees, Pub. Affairs, will receive bids until Jan. 30 for the construction of a earthen reservoir, auxiliary pumping station and water filtration and sedimentation plant. Estimated cost, \$25,000. W. T. Sherman & Co., Toledo, engr.

Pennsylvania

BELLWOOD—The Natl. Steel Constr. Co., 237 4th Ave., Pittsburgh, purchasing the plant of the Bellwood Eng. Co., here, and plans to enlarge and equip same for the manufacture of electrical equipment for the production of fabricated steel plate. S. Kazorski, Bellwood, mgr.

South Dakota

PIERRE—The State plans to construct a cement plant at Lime Creek. Estimated cost, \$100,000.

Texas

DALLAS—The Gulf Refining Co., Frick Annex, Pittsburgh, Pa., has awarded the contract for the construction of several 1- and 2-story buildings, to Bowden Constr. Co., Galveston. Cost between \$150,000 and \$200,000.

Wisconsin

BLACKCREEK—The Outagamie Limestone Co. is having plans prepared for the construction of a plant. J. B. Huhn, Secy.-Treas. H. O. Weldon, 10 La Salle St., Chicago, Ill., archt.

HARTFORD—City is having plans prepared for the construction of a sewage disposal plant and intercepting and storm sewers. Estimated cost, \$100,000. J. Donohue, 608 North 8th St., Sheboygan, engr.

TAYCHEEDA—The State Bd. of Control of Wisconsin, Capitol Bldg., Madison, receiving sealed proposals for furnishing 1 cold process water softener of 3,000 gal. per hour capacity for Wisconsin Industrial Home for Women, here. J. G. D. Mack, state ch. engr.

NEENAH—The Wolfax Co., Main St., plans to construct a 4-story, 60x150-ft. factory for the manufacture of pottery and porcelain ware. Estimated cost, \$80,000. Architect not selected.

PLYMOUTH — City is having surveys made for a sewage disposal system. J. Donohue, 608 North 8th St. Sheboygan, engr.

REEDSEBURG—Bd. Educ., c/o A. Bolson, plans to construct a 4-story, 60x185-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$125,000. Architect not selected.

British Columbia

VANCOUVER — The Harrison Pulp & Paper Co., will construct a mill for the manufacture of kraft paper at the mouth of the Harrison River. Estimated cost, \$3,000,000.

New Brunswick

ST. GEORGE—The New York World Publishing Co., 63 Park Row, New York City, has purchased the plant of the St. George Pulp Co. here, and plans to enlarge same. The plans call for an increased output of from 30 to 100 tons daily.

Nova Scotia

HALIFAX—Silliker & McMann, Cragg Bldg., have purchased the pulp mill and timber property at Hartville and plan to rebuild the plant. P. H. Moore, local mgr.

WOLFVILLE — The Gaspereau River Light, Heat & Power Co. plans to build a 10-ton dry ground wood pulp mill.

Ontario

CORNWALL—The Can Linoleum & Oil Cloth Co., plans to construct a 2-story addition to its plant. Estimated cost, \$35,000.

CORNWALL—The Howard Smith Paper Mills, Ltd., 138 McGill St., Montreal, will receive bids in the spring for enlarging its sulphate plant, here, increasing output to 50 tons daily.

IROQUOIS FALLS — Abitibi Power & Paper Co. plans to enlarge its plant. Estimated cost, \$250,000.

PETERBOROUGH — City will receive bids about Feb. 1 for the construction of a 6,000,000-gal. filtration plant and a 2,000,000-gal. reservoir. Estimated cost, \$350,000. R. L. Dobbin, water-works, supt.

PORT ARTHUR — The Kaministiquia Pulp & Paper Co., Ltd., will receive bids in the spring for building a new pulp mill which will have 250 tons daily capacity.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its annual meeting Feb. 21 to 24 at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting Feb. 14 to 17 in New York City.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

COMMON BRICK MANUFACTURERS' ASSOCIATION OF AMERICA will hold its annual meeting at the Hotel Pennsylvania, New York City, Jan. 31 to Feb. 4.

NATIONAL PETROLEUM CONGRESS will meet at the Hotel Baltimore, Kansas City, Mo., March 22 to 25.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

THE SEVENTH EXPOSITION OF CHEMICAL INDUSTRIES will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: Feb. 11, American Electrochemical Society, joint meeting with Society of Chemical Industry, American Chemical Society and Société de Chimie Industrielle; March 11, American Chemical Society, Nichols Medal award; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Dividing the Sheep From The Goats in Research

MOST interesting men have opinions, and if we look for them we can find them. In reading over lately a number of scholarly addresses on research by Dr. JOHN J. CARTY, vice president of the American Telephone & Telegraph Co., we find a clearly marked conviction that is indicated in all of them and which opens up an interesting and almost endless subject for debate. It is doubtful if in this or any other country there is so large a sum expended annually for industrial research under the supervision of any one man as is done under the supervision of Colonel CARTY. He is familiar with the haunts of discovery as well as with a great number of problems of applied physics, chemistry and mechanics, and he has participated in the solution of many of them.

In all these writings we find the line drawn between research in pure and in applied science. Pure science, to his mind, is properly the subject for research in universities—which includes colleges of technology—whereas research in applied science belongs within the scope of study of industrial and commercial laboratories, institutions and consultants. This is a general statement of his attitude which includes the frank admission of exceptions. It is not an infallible rule. It is a rather a general principle designed to serve as an aid to progress, while experience and common sense should prevent it from becoming a hindrance. Even in a discussion of research any rule of thumb will only mislead us, while headwork is constantly necessary.

The distinction which he draws is not between things done; the electrical engineer, as he says, may work to remove an objectionable feature in electric lamps, while the man of pure science may investigate precisely the same phenomenon in precisely the same manner for the entirely different purpose of obtaining an explanation of a physical occurrence, the nature of which cannot be explained by known facts. The only difference in the work of the two men is one of motive. As another indication of this division we quote from his presidential address at the thirty-third annual convention of the American Institute of Electrical Engineers in Cleveland.

"The investigator in pure science," he said, "may be likened to the explorer who discovers new continents and islands or hitherto unknown territory. He is continually seeking to extend the boundaries of knowledge.

"The investigator in industrial research may be compared to the pioneers who survey the newly-discovered territory in the endeavor to locate its mineral resources, determine the extent of its forests and the location of its arable land, and in other ways precede the settlers and prepare for their occupation of the new territory."

As the same gentleman stated on another occasion, "I would not try to divide science up into two kinds, but rather divide research into two kinds—that is, research conducted from a pure science motive, and research con-

ducted with the applied science motive. The ethics and methods of procedure in these two cases are in many respects conflicting when this distinction is not made. When the distinction is made, the conflict disappears and harmonious co-operation is obtained."

Now temperament will guide motives better than motives will guide temperament, and with the division made, as Dr. CARTY would have it, the two fields call for different temperaments. The man who works in pure science must have what he calls the Divine Spark and what we are disposed to call the Gift of Curiosity, to make him persevere as a seeker after the truth; who can sense what HUXLEY called "the supreme delight of extending the realm of law and order ever further toward the unattainable goals of the infinitely great and the infinitely small, between which our little race of life is run."

We must be constantly on our guard not to let the distinction run away with us, or to draw from it such conclusions as were not intended. Nothing was further from Dr. CARTY's thought than the abolition of engineering and technical schools. Engineering is a profession which has to do with the application of science, and this profession has certain fundamental principles which require study before practice. The distinction has to do with research only, and not with the practical training of students, which is greatly to be desired. His point is that in research it is pure science that should be the field for institutions of learning; that specific problems in industry, if worked out in university laboratories, narrow the general field of study for those under instruction and call for more intimate contacts between laboratory and plant than are possible in universities; that the frank and free exposition of needs, costs, applications, etc., is not so available to the university staff and students as to the industrial laboratory, whether privately supported or privately retained.

Therefore, without desiring to put a brake on progress, he would make a division wherever possible—allot the fundamental problems, the questions in pure science, to the universities, and support them generously. This he regards as a legitimate expenditure by corporations and firms. It is work which universities are peculiarly fitted to perform. The vast number of undetermined chemical and physical constants that are needed almost more than anything else and which are so slow in coming out are within this domain, and university laboratories all over the country should be busy with them. The industries could well afford to pay for it.

Apart from this, however, the general fields of the unknown are so very great that, as a scientific nation, we need this constant study and research in pure science for the inspiration of progress. If the universities look too hard for practical uses; if utility is the motive rather than the all-embracing curiosity to increase the boundaries of knowledge, then the scope of research is

bound to be so restricted that we shall miss the big things. In other words, whenever in pure science we want to be too practical we put on blinders.

This is the trend of thought we read in Dr. CARTY'S various utterances and in which we heartily concur. It is opposed to an equally earnest disposition on the part of others to co-ordinate universities and industries so that, to use a popular expression, they interlock.

If universities are to become great consulting establishments, they must adjust their work to problems of consultation. Here we return to the question of motive. A great industrial consulting and research establishment must have service to industry as its primary motive. If it attempts to train students, the motive to train them must become secondary and not primary; and if students are trained "on the side," as it were, their training is likely to suffer. While it is very desirable for professors of pure science to get out into the industries to see their science applied, their real business is to teach fundamentals and research in pure science.

Sursum Corda

IN AN article on "The Future of the Cotton Industry" in a late number of the *Atlantic Monthly*, Professor MELVIN T. COPELAND of Harvard University tells how the prestige of English cotton mills has been endangered during the last year from a cause which is all too familiar over here, but which applies to other industries as well as to textile mills.

"As a result of the inflation of values," he says, "arising from credit and currency conditions in England, the nominal worth of cotton mills rose far above their original cost. Financial promoters grasped the opportunity to enter the industry. Mills were purchased at what, in the long run, is likely to prove exorbitant prices. Amalgamations of mills have been formed that we should call 'trusts' with heavy capitalization." They have grown beyond manageable size. Heretofore managers of mills have been part owners. They were competent, and the overhead expense for good management was slight. As partners they gave time and divided profits. With the sale of the properties these experienced managers have been supplanted and the establishments have grown too big for the eye of any other master than an industrial genius. The need to pay dividends on excessive capitalization works against proper maintenance and upkeep. This same excessive capitalization increases unrest among the workers of the mills, and the industry is thoroughly unionized, with fifty years' experience in collective bargaining. Then follow troubles and strikes and losses and the discouragement of other investors.

We have had so much experience with this very type of mismanagement of industry in this country that no warning should be needed, but it seems to be, all the time. Just because great corporations organized with scrupulous care do succeed occasionally is no reason why loosely jointed units should make for consolidated success. The incidence of greatest fault is usually upon so-called investment bankers who do not know one industry from another. The consolidation of interests into great corporations is sound only when all the talent and interest is held close to every job and all the fear of making mistakes is kept alive in the heart of every department chief while at the same time encouragement for work well done is constantly studied and applied.

Sursum corda, lift up your hearts, is an old ecclesiastical shibboleth, but it is needed in industry as well. As soon as it weakens, as soon as the men engaged cease to feel the inspiration that they are responsible parts of something alive and vital, their hearts sink. Then somebody else with a small establishment that he understands and can manage well and who has his heart in his work will naturally undermine the big concern and get its business.

Opportunity for Engineer-Citizens

THOUGHTFUL readers will be impressed, if not depressed, at the revelations made by RAYMOND B. FOSDICK in his book on American Police Systems. Whenever we are disposed to let the eagle scream and thank the LORD that we are better than other folks, it may be worth while for our own illumination and better understanding to ponder over a few of the statistics which the book contains. We present a few of his figures without further introduction:

In 1918 the arrests made in Boston, Philadelphia, Chicago and New York exceeded those made in London during the same year by 32,520, 20,005, 61,874 and 111,877, respectively. In 1919 there were 5,527 automobiles stolen in New York against 290 in London and ten in Liverpool—better than fifteen a day in New York as against less than one a day in London and Liverpool. In 1918 the ratio of robberies in London to those in Chicago was as 1 to 22, and there were in that time fourteen robberies in Chicago to every one in all of England and Wales. But not only have New York and Chicago been wallowing in the muck of misgovernment during the past few years, achieving such unhappy distinction. There's Los Angeles, that had in 1916 sixty-four more robberies than England, Scotland and Wales combined. Cleveland has three-fourths the population of Liverpool, and last year reported thirty-one times as many robberies. In 1917 Chicago had more murders than England, Scotland and Wales together.

"Well," as the late WILLIAM M. TWEED asked, "what are you going to do about it?" What shall we do? Go right on boasting and bragging and letting things go to the devil? Haven't we as engineer-citizens any responsibilities? The majority of crimes are committed by young men; men under twenty-five years of age, as we recall it. A few years ago these boys were toddling about the streets; most of them in this country. Those that were born abroad might not have engaged in careers of crime if they had not come over. The fact that they did engage in crime here is our fault. It's pretty hard to tell just what the fault is, but it rests upon us all. In a little while the boys that are now toddling about the streets will have reached the criminal age, and their ideals are at present in the making. Have we any means of molding these ideals into good citizenship? If we have, isn't it about time we began to think about doing some of this molding and getting it done?

One thing is certain, and that is that we can't lead these young criminals into enlightenment by legislation. The more laws we make the more they'll break. The most hopeful means now available seems to be in the organization of boys' clubs, plenty of boys' clubs, under competent supervision. An immense number of these are needed, and they can't be run by machinery; they

require, each, a sympathetic, firm, intelligent and sporty director. One of the best and most successful leaders of boys we know is a chemical and metallurgical engineer whose hobby is good citizenship through the Boy Scouts movement. Other engineers might follow his example with profit to themselves and the community. Given the right men in charge, gangs disappear from the neighborhood. The gang is the principal nursery for our criminals.

Efficiency in Freight Movement

WHAT a diversity of counsels there is with respect to our railroads! There are those who argue that now is the time for the railroads to buy, so as to act as business stabilizers. There are others who insist that now is the time for the railroads to economize and develop efficiency. In one quarter it is urged that shippers should ship now if they can, for later there may be great delays. In other quarters the feeling prevails that the heavy freight rate advances of last August were accepted cheerfully by the public because they promised better freight service, so that consumers would not need to carry stocks.

One of the chief sources of trouble is that many people have ulterior motives. They think of the railroads not as servants of the public but as patrons. They are less interested in seeing the railroads furnish good service than in seeing them place large orders. They have noticed in the past that when railroads were large buyers business was good, hence they assumed that these things stood in the relation of cause and effect. If it is a case of *post hoc, ergo propter hoc*, it would be more to the point to note that every industrial depression we have had has been preceded by a period of marked railroad expansion, either in building new road or in adding to equipment.

In our issue of Nov. 10, 1920, reference was made to our troubles about coal, the explanation proposed being that the coal industry had grown so large that it could not grow the way people wanted it to because it was beginning to interfere with other industries. This same principle applies to railroading, and will apply to any activity in similar circumstances. In fact, the principle applies even more pointedly to railroading than to coal mining, for as indicated in the discussion as to coal the rate of increase in production and consumption has been tending to decrease, whereas in railroading the rate of increase in freight ton-mileage has shown no signs of coming down.

All along the line, moreover, the tendency in the past few years has been for men connected with the railroad service, whether on the railroads or in shops serving the railroads, to do less work. Incidentally there are the full crew laws, the Adamson law and the abolition of piece work. Last summer there was loud complaint that railroad service was insufficient. We could not build enough roads because road material was lacking, we could not build enough automobiles, we could not make enough steel, we could not do enough anything, because we hadn't enough railroad facilities to move freight. Yet everybody was at work. There were more jobs than men. What would have occurred if there had been twice as much railroad capacity? There might have been twice as many jobs, but there would have been still fewer men working at the jobs, because more would have been working at railroad jobs.

Obviously, then, what is needed is more efficiency at both ends. The railroads should handle more freight per unit of equipment and per man employed, and the public should get along with less freight movement in proportion to its industrial activity.

Conversion of Sawdust Into Cattle Feed

ON ANOTHER page E. C. SHERRARD tells of his experiments in making cattle feed from sawdust, which is interesting from several points of view. He secures a conversion of about 20 per cent of the wood into sugar, which seems large from the published records of the producers of alcohol from this source. It would be interesting to know how large a part of these sugars is fermentable. The extraction of the sugars from the digested dust and the evaporation of the sugar solution to a thick sirup are processes which, it would appear, might be done at the sawmills, whether the product is to be fed or fermented. Mixing the sirup with the wood residue seems to indicate a plentiful and eventually a cheap fodder, for the cows get all there is to the sawdust, while nothing but the moisture in the mixture is wasted.

When the fodder consisting of 26 per cent of hydrolyzed sawdust was administered, the cows gave an increased production of butter fat and they gained markedly in weight. The "wood meal" was substituted for barley in the ratio of 2 to 1, the cattle obtaining their protein from the other parts of their ration which was mixed with it, for the protein content of sawdust is admittedly light.

The experiment was made with Eastern white pine. We have no idea what would happen if hemlock or oak sawdust were used. Maybe the pine wood meal contains some kind of vitamine that makes cows give milk, although Mr. SHERRARD doesn't say so. That the cows were fed by the "reversal method" worried us until we discovered that *reversal* is a stock breeder's technical expression for *alternating*.

The Chemical Engineer And the Human Viewpoint

IT IS SAID of many chemists and other scientific men that they are lacking in an appreciation of human relations, that they are unsociable and that they need a training in personal salesmanship. This cannot be true of the successful chemical engineer. If he is to carry the ideal of winning the top notch for the benefit of chemistry to the industries he must have, above all knowledge of the phases of business, a human sympathy and understanding of men.

This has been said before regarding success in other ways, but it should be practiced. The man in the plant does well to lunch with the laborers, discuss with them the things of interest in their lives. It is entertaining as well as profitable. Some practical philosophy may be instilled by conversation but without preaching. If a wheel becomes stuck during the work, the chemist may well throw in his shoulder, even though he may dirty his Sunday clothes. Later on when gentlemen are subordinates on his staff he will have acquired the ability to be kind and considerate. The main difference between the office man and the laborer is a mighty thin polish. Elementally, they are alike. Finally, when subordinates feel that the executive chemist is with them, he is qualified to sit in high places.

Readers' Views and Comments

Electric Furnace Refractories

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to Mr. Greaves-Walker's reply to my comments on "Electric Furnace Refractories" (CHEMICAL & METALLURGICAL ENGINEERING, Dec. 22, 1920, vol. 23, p. 1196), I am sorry that Mr. Walker received the impression that I intended to ignore the existence of certain dead-burning plants in the Eastern United States which were put into operation before the plant of the Northwest Magnesite Co. Such was not my intention, as I was referring to magnesite producers and the Northwest Magnesite Co. *was* the first magnesite producer to erect a dead-burning plant at the mine.

The plants to which Mr. Greaves-Walker refers ceased operations when the Northwest Magnesite Co. began producing dead-burned magnesite, because there was no economic reason for their existence. If they burned crude magnesite they would have to pay freight on the CO₂ gas shipped into the plant, and if they reburned calcined magnesite they would have to stand the cost of a second handling and burning. Aside from any other considerations, therefore, their operation was impractical as soon as properly made dead-burned magnesite was produced at the mine. ROBERT D. PIKE.

San Francisco, Cal.

Relationship Between Segregation and Rail Failures

To the Editor of Chemical & Metallurgical Engineering

SIR:—Dr. Burgess' recent series of articles on comparative rail tests has doubtless aroused considerable interest among your readers, but I do not think you are quite fair to Dr. Burgess in your editorial entitled "Good Rails Are More Than Sulphur Prints." This statement is, of course, true, as Dr. Burgess also would readily admit, but the following statement that all the rails that he tested were good is open to very serious questioning. I would like to emphasize that goodness in a steel rail implies much more than resistance to wear; a worn-out rail can easily be replaced when its appearance shows it has become weak, but the damage done when a good-looking but brittle rail breaks under a fast train is a very serious matter.

It is a great pity that Dr. Burgess' careful testing of these rails was not followed to its logical conclusion of a service test on the basis of safety or resistance to breakage, instead of merely wearing them out by excessively heavy traffic before they had a chance to fail from cracking or fatigue. But the omission of such a test in this case is hardly a good reason for your sweeping criticism of metallographists and testing engineers who have found out by study and experience what defects usually make rails fail in service and who thus feel justified in classing rails without these defects as better than those which contain them. Sulphur prints are probably the most valuable and trustworthy means of showing one of the most dangerous of these defects—namely, segregation. If the drop-test does not reveal these defects clearly, Dr. Burgess has done well in calling attention to its limitations.

Another point which you have apparently failed to

consider, in stating that all the rails tested by Dr. Burgess were good because no failures in track were reported, is that the bad portions of all these rails were cropped off during his careful inspection and search for segregation, piping, etc. It is hardly necessary to state that discards of 60 per cent, or even of 30 per cent, are unheard of in ordinary rail-mill practice, so that in making these discards from the defective ingots the rails which might be expected to break in service were eliminated.

I am in hearty agreement with your statement that Dr. Burgess' tests are "probably the most minute study ever made of a rail rolling," but they are open to the objection from a practical standpoint of having been concentrated on comparatively few ingots and rails. This is admitted in his discussion of "performance in service" on page 1021 of your issue of Nov. 24. On this account I would like to call attention to the series of tests made a few years ago in our laboratories on samples of A-rails from a number of rollings at different mills.

These tests were made to determine the general effect of titanium treatment of rail steel, and the samples were obtained in pairs, the same number of titanium-treated A-rails and of ordinary untreated A-rails being obtained from each mill, from rollings as near together as possible, and with the same top-discard, usually 9 per cent, from both kinds of steel.

Tests made on these rails included chemical analyses, tensile, hardness, impact, endurance and vibratory tests at various parts of the rail section, and also metallographic studies both by macroscopic etchings and by examinations of non-metallic inclusions and microstructures with a microscope.

The average results obtained from the physical tests were as follows:

		Plain Steel	Treated Steel
Elastic limit.....	Head	56,936	59,441
	Flange	57,005	59,841
Tensile strength.....	Head	119,900	125,723
	Flange	121,523	126,370
Elongation.....	Head	12.9	13.5
	Flange	15.3	15.1
Reduction of area.....	Head	14.3	16.0
	Flange	18.4	19.2
Brinell hardness.....	Head	219	224
	Web	249	235
	Flange	215	225
Impact resistance.....	Head	1.48	1.60
	Web	1.11	1.24
	Flange	1.29	1.44
Endurance test.....		20,404,456	27,501,196
Vibratory test.....	Head	1,275	1,252
	Web	919	1,047
	Flange	1,310	1,236

We determined from these tests that the essential improvement obtained by titanium treatment consisted in the elimination of segregation, without any simultaneous contamination of the steel by a deoxidation product such as alumina or silicates. We then made a much more extensive test of smaller samples of A-rails, both treated and untreated, to determine how general and infallible this action of our alloy on segregation was. This investigation was made by sulphur prints

and by chemical determinations of carbon at an upper corner of the head and just above the junction of head and web. Excessive segregation, accompanied by a streaky condition as indicated by sulphur prints, was found surprisingly prevalent among the samples examined from 111 different heats of ordinary untreated steel, but it was rare among the titanium-treated samples, which came from 101 different heats.

	Plain Steel	Treated Steel
Total number of heats.....	111	101
Number with less than 1 per cent segregation.....	6	29
Number with 1 per cent to 12 per cent segregation.....	34	65
Number with 12 per cent to 20 per cent segregation.....	27	5
Number with over 20 per cent segregation.....	44	2

We have continued our work in examining numerous other heats of titanium-treated steel for segregation, and we still find it rare in this class of steel. We have found, moreover, that no titanium-treated rail is ever segregated if the treatment has been properly made so that there is a small residual content of titanium. Segregated titanium-treated A-rails always show a titanium content below this required minimum. We feel that this is rather an important discovery, affording a simple practical test whereby the purchaser of steel rails may be assured that his material is free from segregation.

I would like to emphasize the above in comparison with Dr. Burgess' results on segregation. From the thirty-six sink-head ingots, seven of the A-rails showed over 20 per cent segregation and seven others showed between 12 and 20 per cent. In other words, 42 per cent of the sink-head A-rails showed over 12 per cent segregation, while only 7 per cent of our titanium-treated A-rails were similarly segregated. The average discard necessary for segregation from the sink-head ingots was 11.5 per cent, while our titanium-treated samples were cut after an average discard of 9 per cent. It is true that the Maryland comparison ingots killed with aluminum required a smaller discard for segregation than 9 per cent, but their additional discard for pipe was excessive. Theoretically there is no question that the sink-head process is effective in eliminating pipe from ingots, but piping can be controlled also by care in the ordinary methods of ingot manufacture. For instance, in a recent rolling of standard titanium-treated rails, the top discard averaged 8.3 per cent from the ingot, and by keeping the silicon content of the steel below 0.10 per cent and pouring the ingots slowly, the piped rails were kept down to 4.5 per cent, as determined by the nick-and-break test on every ingot. No special molds or hot-tops were used.

It has been brought out by some of the American Railway Engineering Association's reports and those of the bureau of safety of the Interstate Commerce Commission, that split heads and webs, which constitute about half of the causes of rail failures, are due to segregated streaks and generally occur in the A-rails. This, of course, is the reason why it is so important from the standpoint of safety to eliminate segregation from rails. The head failures for 1919 constitute over half of the total. An I. C. C. committee has recently reported that "seaminess plays an important part in many rail failures, the elimination of which or partial

success in their avoidance should reduce the number of failures." This seaminess has been shown to be merely a form of segregation and is nearly always indicated by sulphur prints of ordinary A-rails. "Accident Bulletin No. 84" of the Interstate Commerce Commission states that 631 accidents in 1919 were attributable to broken rails and ten persons were killed in them. Of the rail accidents whose detailed causes are given, almost 70 per cent were due to "crushed heads, split heads or split webs," all the result of segregated steel without much doubt. The practical importance of avoiding segregation in steel rails should therefore be evident to all.

We are in a somewhat stronger position than Dr. Burgess in regard to actual service tests, for all the titanium-treated rails that we examined for segregation with the results noted above have been in track long enough to give an accurate idea of their average endurance. We have taken all these service records directly from the rail failure statistics of the A.R.E.A. The average data taken from the 1918 report for open-hearth steel only will be given here. The average failures per year in service per 100 track-miles were 6.8 for all titanium-treated open-hearth rails. For ordinary untreated rails the best showing from any mill was 8.7 failures per year in service per 100 track-miles, and this was for rails from a mill where it is understood the A-rails are discarded and rolled into small bars for miscellaneous uses. The records from other mills for untreated rails were 9.0, 12.7, 14.0, 15.0, 15.2, 15.3, 16.3, 16.5 and 26.2 respectively, the average record for all untreated rails being 14.3. Thus the failures in service of titanium-treated open-hearth rails were only 48 per cent of those for ordinary untreated open-hearth rails, which proves that by eliminating segregation we have indeed prevented half the rail failures.

Since the above data were tabulated, the rail failure statistics for 1919 have been published, and we find a different set of figures, since these reports cover only the rails that have been in track for five years or less, and hence each year the oldest lots from the year before are dropped. Also in this report the bessemer and open-hearth rails are grouped together and not kept separate as formerly. Six lots of titanium-treated rails are included in this report, and four of them stood five years' service with no failures, one stood four years' service with no failures, and one stood five years' service with thirteen failures, nearly all of which were flange breaks or clean transverse fractures, as reported to us by the railroad. These failures average up to the very low figure of 3.3 per 100 track-miles per year. Two lots of sink-head ingots are also shown in these rail failure statistics, one of them giving twenty failures in five years' service and the other eleven failures in four years, making an average of 12.2 failures per 100 track-miles per year. The averages for all rails from the various mills were respectively as follows: 8.4, 8.5, 11.9, 12.0, 13.4, 15.6, 19.3, 19.4, 22.5 and 41.7, giving a grand average of 14.7. The showing for the sink-head ingots is thus very little better than the average, while the titanium-treated steel showed only about one-fourth of the average number of failures per 100 track-miles per year and less than half as many as the ordinary rails from the mill that had the best record of all.

An Account of the Expansion of the Scope and Facilities of the Research Department of The Barrett Company—Study of Physical Properties, Methods of Testing and Development of Synthetic Products

BY JOHN MORRIS WEISS AND CHARLES RAYMOND DOWNS

A STUDY of the recent *Bulletin* of the National Research Council by A. D. Flinn entitled "Research Laboratories in Industrial Establishments in the United States of America" is indeed gratifying, as it indicates the widespread appreciation of research by the industries of the country. Industrial research laboratories have greatly increased in numbers and size in the last few years. The great improvements in both quality and diversity of products already evident should result in accelerating advances in the near future as these laboratories gain more experience in attacking the problems vital to the betterment of national security and independence.

To accomplish this desirable objective it is imperative that the brilliant young minds of the country appreciate the fascinating game of research and be attracted to it in proportion to its importance as a national insurance. It is also vital for the faculties of our universities to realize that in the past they have been perhaps too prone to evaluate their students upon the basis of memory and upon parrot-like repetitions of the contents of textbooks. Chemical research needs men with creative imagination who are sufficiently familiar with the work of the past so that new advances can be made by studying the effect of materials under new conditions, by examining common materials with improved instruments, by the study of manufacturing wastes, by noting and developing the byproducts of research which may be of more importance than the objective originally conceived.

Many of the most important discoveries of science have been so-called accidental, but had the power of observation and creative imagination been lacking they would have remained unknown for generations. We must admit that a knowledge of the literature is of very great importance, but that even the simplest experiments

reported in the past may have produced an important unrecognized byproduct. For the proper prosecution of such work the mind running in a groove along conventional lines is unproductive of revolutionary discoveries.

We therefore cannot rate or compare industrial research or any other research laboratories by the number of men employed or by the imposing expenditures of money assigned to their construction. Men trained in the fundamental principles of science and retaining mobile, plastic minds are the great unfilled need. The progressive industries are ready enough to supply the proper laboratory equipment and the business organization of the laboratory to relieve the research man of the executive and routine details.

PHYSICAL STUDY OF COAL TARS

The coal-tar business touches in some more or less personal way a great proportion of the manufacturing of modern civilization, and its scope is broadening daily. We have only a dim appreciation of its possibilities even after 150 years of destructive distillation of coal. The officers of The Barrett Co. sensed that there were still great potential treasures locked in the dingy tar vault and that long sustained attack would conquer the vault combination. The process of picking this lock is a fascinating problem and it is only partly solved, although numerous tumblers have shot home during the history of coal-tar chemistry.

In 1911 The Barrett Co. made a small beginning at a systematic study of the research problems connected with coal-tar industry when it established a research department. In the initial stages the work naturally concerned itself with the study of tars obtained from different sources and made by distilling coals in various ways. A large amount of data was collected along these lines. Such data are essential to the proper utilization

of tar in the manufacture of cruder products, so that tars can be properly blended before distillation to obtain desirable properties in either the residuals or the distillates. Further, in the production of the more refined products, the nature of the crude tars often predetermines their adaptability and use for the manufacture of such products. As the properties of coal tars are continually changing, depending upon the economic conditions which influence the methods of coal carbonization, this problem is a continued one and studies along this line will probably be a permanent part of work in coal-tar chemistry so long as such changes take place.

Naturally also a considerable amount of study was and is being given to the development of suitable testing methods for tars and the various primary materials separated from tars. Many of these testing methods have been described by one of the authors in the *Journal of Industrial and Engineering Chemistry* of September, October, November, and December, 1918, and a number of these methods have been accepted by the American Society for Testing Materials, the American Gas Institute and other technical associations in a substantially unchanged form.

SYNTHETIC CHEMICAL INVESTIGATIONS

As to the work along more strictly chemical lines it is, of course, impossible in a paper of this sort to give very much detail, as naturally such work is of a decidedly confidential nature, so that we can give merely a few examples of developments which will indicate the considerable scope and breadth of the work carried out in the research department of The Barrett Co. Among developments which have reached a full manufacturing scale are: the complete synthesis of alizarin or turkey red; the synthesis of phenylglycine, an intermediate for the manufacture of indigo; and resorcinol, used largely in dyes and hair tonics. The development of catalytic oxidation processes have recently resulted in new manufacturing methods for the production of anthraquinone, phthalic anhydride, maleic, fumaric and malic acids, and these are all being manufactured on a small scale somewhat beyond the experimental laboratory stage.

In addition to the work at the research laboratory

NEW LABORATORY BUILDING, ENTRANCE TO BE CENTER OF COMPLETED STRUCTURE

much work has also been done at the laboratory of our chemical department in Frankford, where the Dennis-Bull process for the manufacture of synthetic phenol was developed. Products such as orthocresol, Cumar (coumarone resin) and alpha-naphthylamine have been developed and produced on a large scale. The development of column distillation made it possible to separate orthoxylene from the meta- and para-isomers and produce this as a commercial product. Much investigation has been done on improvements in the manufacture of naphthalene and in the production of high-purity anthracene, carbazol and phenanthrene.

Similarly, methylnaphthalenes, acenaphthene and fluorene have been produced, these awaiting only commercial uses to make their production an accomplished fact. Synthetic tanstuffs have been studied and several grades of satisfactory commercial quality are being manufactured. Another branch of the work of a very different nature has been in the development of disinfectants, which requires bacteriological work as well as chemical work. As a result disinfectants of

LABORATORY IN OLD BUILDING

extremely high germicidal coefficients have been produced.

Also, apart from the research laboratory, there has been considerable development at our various branches in the manufacturing methods as applied to the cruder products. Great improvements in the art of tar distillation have been recorded. Considerable work has been done on paper, as in the manufacture of our saturated felts we have naturally become paper manufacturers on a large scale. Development and investigation have been necessary in these fields and in all of them the research department has co-operated both in an advisory capacity and also with practical experimental work.

As a byproduct of some of this work, a centrifugal machine has been developed whereby bituminous materials and other products can be produced in hair or

present there is a total force of about 100 men in the research department.

Although all of the buildings shown in the sketch are in use, we will describe only a few of the salient points of the new research laboratory. It is built of reinforced concrete with tapestry brick panels.

THE NEW LABORATORY BUILDING

The front member of the L form comprises the office section and is separated from the laboratories, which are situated in the other member of the L, by rolling shutter fire doors released by fusible links. In addition to the fire escapes prescribed by law there is a fire balcony connecting the windows of the various laboratories above the first floor, so that egress is provided from each room both by the doors leading to the corridors and by the windows. Every laboratory in which

shot form. This apparatus is applicable to other substances with suitable melting points and forms a very excellent means of subdivision and cooling.

EXPANSION OF THE RESEARCH DEPARTMENT

Today the tendency is to centralize as far as practicable as much as possible of the varied work at the laboratories of the research department. These have expanded in size from 816 sq.ft. floor area in 1915 to 29,000 sq.ft. in 1920, the comparison being shown in a figure accompanying this article. The sketches do not include some experimental plant buildings which are at present occupied actively on research problems. The new laboratory, built in 1920, is laid out for a possible expansion to a total of 54,000 sq.ft. of floor space, allowing for the accommodation of more than 210 working laboratory chemists in addition to other chemists and chemical engineers in the experimental plants. At

flammable organic materials are in use should be provided with two exits, as a fire may take place in front of one and thus block off the escape of the occupants in that direction.

Shower bath heads are also placed in each laboratory room for the purpose of extinguishing burning clothing or for removing splashes of corrosive liquids. These are provided with chains fastened to a pipe cross-bar so that the water may be released without difficulty in times of accidents. No drain is provided in the floor, as the use of these showers should be very infrequent. Fire blankets are also provided on vertical rollers similar to window-shade rollers so that a man can wrap himself with the least loss of time. A trained fire department and first aid committee are provided. All laboratory rooms are supplied with Foamite and Pyrene extinguishers, sand pails and fire horns, by means of which equipment practically every small fire can be controlled.

The table frames are made of cypress timbers. The floors of the laboratories are of maple laid over concrete. This sort of construction permits simple fastening and staying of miscellaneous semi-fixed apparatus. Alberene tops are used on the tables. The walls are of Pyrobar, plastered and painted with Toch's White Enamel Laboratory Paint. These walls will hold nails, hence shelves or miscellaneous small apparatus may be easily erected without resort to drilling and the use of expansion bolts. After removal of a shelf the holes are easily patched. Glass partitions of standard construction are used throughout for the offices.

Much care was exercised to provide efficient lighting for the new laboratory. The windows are large, being 6 ft. 7 in. high by 4 ft. 2 in. wide. For the artificial lighting the lamps are placed in relation to the tables so that the worker does not work in his own shadow. The

arrangement prevents the ingress of dust from the outside. Outlet for the foul air is provided through the hoods.

Each hood is provided with a separate exhaustor and this discharges directly through the wall of the building to the outside, thus obviating the carrying of large exhaust ducts throughout the building with their liability of corrosion. Only under extreme conditions is there any necessity for operating the individual hood exhaustors, as the air supplied by the ventilating system induces sufficient draft through the hoods.

All of the piping in the building is exposed and easily accessible in case repairs are necessary. The piping system comprises drains, hot and cold water, compressed air, gas and high- and low-pressure steam. Portions of the pipes and valves are painted with distinctive colors denoting their use. Such practice allows of quick shut-

question of artificial lighting is important so as to obtain sufficient light well distributed without so much concentration in any one place that eye strain will develop from glare. To assist in this desirable objective the wall as the back of wall tables is painted with a black enamel to the height of 2 ft. above the table. Direct illumination is used as the cleaning of the bowls of indirect lighting is too laborious.

The ventilation of the laboratory rooms is accomplished by discharging into them air heated to 60 deg. F. in cold weather, and whenever additional heating is necessary radiators placed in the individual laboratories may be used. The air of the laboratories is renewed approximately every two minutes and drafts are obviated by special deflectors and by a multiplicity of air inlets wherever needed. There is, therefore, no necessity for open windows and hence the air pressure in the rooms is above the atmospheric pressure. This

off of gas lines, for instance in case of fire. The tables are provided with numerous electric power plugs for the operation of motors, ovens and the like.

A duct extending from the basement up through the building, denoted in the sketch as A, allows temporary electrical or pipe lines to be brought up to a particular laboratory for specific work which is not cared for by the standard electrical or piping equipment.

Another novel feature is found in room 66, which is provided for the storage of small amounts of flammable solvents used in the laboratories adjoining. It is provided with steam and hot and cold water for the distillation of very flammable materials, such as ether. A transparent wire glass partition separates it from room 65.

There are both temporary and permanent experimental plant buildings, one of the latter being shown in the sketch. This is equipped with vacuum, com-

TYPICAL ROOM IN NEW LABORATORY BUILDING, SHOWING EMERGENCY SHOWER, FIRE BLANKET ROLL. EXPOSED PIPING OVERHEAD AND AIR INLET PORTS

pressed air, gas, water, high- and low-pressure steam lines and floor drains. The headroom is 18 ft. to the eaves and power shafting is hung from the roof beams. Electric power drop cords are also suspended from the roof to take care of electrically-heated portable apparatus. In this building small-scale plant apparatus may be arranged in proper flow relation by framing.

LARGE-SCALE LABORATORIES

Large-scale laboratory work is provided for in one of the experimental plant buildings. The equipment consists of type apparatus not necessarily arranged in a flow relation as would be used in either an experimental or large-scale manufacturing plant. It is used for preparing batches of materials on a scale considerably larger than laboratory practice, so that sufficient material can be produced to determine its application.

DEPARTMENTAL ORGANIZATION

For the proper allocation and handling of the work the laboratory personnel is subdivided at present, under the chief chemist and assistant chief chemist, into five divisions, namely: tar and oil division, organic research, experimental plant, engineering and clerical.

In order to harmonize the working of the laboratory an operating committee composed of the heads of the divisions, the chief chemist and assistant chief chemist and also other members of the divisions whose ability and loyalty warrant their attendance meets one afternoon each week. It considers in more or less detail, depending upon exigencies, the entire work of the department.

The executive committee, made up of the divisional heads, chief chemist and assistant chief chemist, meets for about one hour once a week to consider questions of general welfare and also to provide an opportunity for the chemists to express their opinions concerning the mechanical service supplied.

Seminars are held occasionally where papers are presented either by men in the department or by sales or manufacturing men. Co-operation not only in the department itself but with the rest of the company is earnestly sought and nurtured, and upon this principle depends the success or failure of any of our large, complex, present-day manufacturing organizations.

The hack work of literature searches is well taken care of by a librarian and library chemist, these jointly

preparing bibliographies and abstracts of all articles in a given field, thus placing the chemist in a position to select his reading intelligently and efficiently.

An entirely different type of research and investigation work being carried on by The Barrett Co. is embodied in part of the efforts of the so-called technical service staff. This staff is composed of trained chemists and engineers and its work is directed from the general offices of the company. Its efforts are devoted to technical problems outside our own four walls, determining and developing possible uses for Barrett products, taking the new ideas in the research laboratory to the outside trades, and bringing to the company suggestions of its own as to new products that may be manufactured.

The physical development of our research laboratory is constantly increasing, as we have not only to deal with the production of new materials and the improvement of processes but also with many problems in which the utilization of our products is involved, and as the field into which our products enter is quite varied this work also is naturally quite varied and requires special types of apparatus, particularly adapted to the industries in which our products are used. Coal-tar products and derivatives roof our homes and factories; protect our roads from disintegration and decay; prevent the attack of fungi and marine bores on structural timber; separate ores from accompanying gangue; disinfect our public places and sick rooms; form part of both preventive and curative medicines; color textiles, leathers, inks and what not in our everyday life; waterproof dams, concrete barges, subways and underground conduits; are found in our chewing gums; furnish power in our internal combustion engines whether on land, sea or overhead; comprise a large part of our military and domestic explosives; assist in making up for the lack of natural crude acids for our beverages; protect our structural steel against corrosion; protect our clothes against moths; enter into the composition of our varnishes, of electrical insulators, of clay pigeons, of case hardening compounds for steel treating, of electrodes for arc lights, electrochemical smelting and manufacture of metallic aluminum; are essential constituents of many of the rubber compounds used in various ways; in grinding lenses for our opera glasses, and in fact, enter into almost all phases of our daily life.

Gasoline by the Charcoal Absorption Process

Description of the Activated Charcoal Process for Absorbing Vapors From Natural Gas—Comparison With Commercial Processes—Activated Coconut Shell Charcoal—Absorption and Selection—Steam Distillation of Saturated Carbon—Yields and Quality of Products

By G. A. BURRELL, G. G. OBERFELL AND C. L. VORESS

TWO methods of extracting gasoline from natural gas—compression and oil absorption—are now used extensively, while refrigeration is used to a limited extent. The charcoal process, a recent development operating on entirely new and scientific principles, compares most favorably with either of these methods. It produces higher yields and a better grade of gasoline. It does not require heavy initial installation costs and can be operated more cheaply. The apparatus has longer life and is not subjected to inefficiency due to wear. Its adaptability to field conditions is enhanced by the fact that it operates on either lean or rich gas at either high or low pressures.

This year there will be practically 300,000,000 gal. of gasoline produced from natural gas. Where the salable vapors in the gas are over a gallon per thousand cubic feet, it is possible to recover a considerable proportion by directly compressing and cooling the entire volume of gas. Where the salable vapors in the gas are not so plentiful, it has been the custom to resort to the oil absorption process, which is simply a method whereby the desirable vapors are concentrated by partial fractionation so that pressure and cooling may be effectively applied as in the original compression process. The gas is made to bubble or flow through absorbers where the gas comes in contact with a high-boiling mineral oil or naphtha which absorbs the heavier fractions in excess of the lighter ones. The oil or naphtha is then subjected to steam or direct heat to vaporize again the absorbed fractions so that they may later be condensed by cooling and compression.

DISADVANTAGES OF THE COMPRESSION AND ABSORPTION PROCESSES

There are several features of the present processes which are considered obnoxious by practical operators.

Both the oil absorption and compression systems require considerable pressure. The oil absorption may be used at low pressures, but it is not considered good practice because of the low saturations which must be adhered to. These high pressures are not only expensive to produce but mean large outlays for repairs and renewal of machinery. They also increase the danger of explosions.

Quite a little difficulty is experienced in marketing the product because of the large amount of so-called "wild" vapors which it contains. These vapors are the lower boiling fractions which have been absorbed and condensed in the higher boiling fractions by the compression, cooling and solvent action of the liquid. It has been apparent to many men for some time that a method whereby a sharp fractionation could be obtained would eliminate much of this trouble. Methods of hot blending and steam treatment have been used with varying success as a substitute for the original frac-

tionation, but all admit that there is still much room for improvement.

The present oil plants are far from simple both in number of units and operation. Constant supervision is necessary if the oil plant is to be operated at as high a degree of efficiency as 75 per cent of gasoline extraction.

From the standpoint of pressures used, of quality of product, of efficiency of extraction, of simplicity of apparatus and operation, and of cost, a new process, one working on an entirely new principle, has been demanded.

CHARCOAL ABSORPTION PROCESS

The charcoal absorption process consists of bringing the natural gas into intimate contact with activated charcoal, in the capillaries of which the vapors are condensed and the dried gas allowed to return to the distribution lines. When a predetermined saturation of absorbed vapors has been attained in the charcoal, the gas is allowed to come into contact with a fresh supply of carbon. The vapors retained in the first mass of charcoal are then evacuated by distilling off with superheated steam, condensed in water-cooled condensers, blended and stored preparatory to marketing. Fig. 1 is a flow sheet diagram of the plant.

ACTIVATED CHARCOAL

The charcoal best suited for the successful operation of the process is made from coconut shells by the steam activation process developed during and since the war. Charcoals made by other methods do not possess sufficient absorptivity to pay for the costs of recovery and therefore are of no use in this process. Even at the close of the war, the better grades of charcoal, those testing from fifty to sixty minutes by the accelerated chlorpicrin test, had not been produced in quantity.

Any charcoal suitable for absorption of vapors from gas must be capable of readily condensing and retaining large quantities of liquid in capillary equilibrium with its vapor and at the same time offer a minimum resistance against recovery. It has been found when applied to gasoline production, if coconut charcoal is activated up to forty, fifty or sixty minutes for the absorption service time, that the retentivity factor tends to decrease above fifty minutes. The curves given in Fig. 2 were obtained with our standard laboratory testing outfit, the glycerine distillation method being used in obtaining the data. It will be noted that there is not a great amount of difference in the maximums of the curves. The big difference is in their decrease in efficiency due to oversaturation. In other words, it is the retentivity function. Fig. 2B shows the same curves corrected for gravity. The twenty-minute material shows a large lack of retentivity, probably due to the shallow capillaries. The fifty-minute

material shows up best here, due no doubt to the capillaries being of the correct size to permit of selection, a term which we shall discuss later. Fifty- to sixty-minute charcoal will absorb from 10 to 15 per cent of its own weight and retain the salable vapors for later recovery.

One very essential feature that the charcoal must possess is what we term selective absorption. Natural gas consists of the gases and vapors of the paraffine hydrocarbon series, the higher members of which have an appreciable vapor pressure at the temperature of the gas. When the gas is first brought into contact with the charcoal the lighter, high-volatile vapors, such as ethane, propane, butane, etc., are absorbed in the capillaries, but as the saturation increases a selection or equilibrium adjustment takes place with the result that these high vapor pressure and undesirable fractions are left in the gas. The heavier fractions are thus isolated and can then be condensed after steam

FIG. 1. FLOW SHEET DIAGRAM OF THE PLANT

distillation without the use of high pressures. Regulation of the vapor tension of the final product is thus obtained by preventing the absorption of the higher boiling fractions.

The size of the granules of charcoal should be from 8 to 14 mesh. Smaller mesh material has slightly greater absorbing qualities, but the resistance to the

gas passage rapidly increases as the size of the granules decreases. Gas flowing through a column of charcoal 5 ft. in depth at the rate of 40 cu.ft. per hr. per sq.in. of base surface and flowing against atmospheric pressure will show a retardation of from 1 to 2 lb. due to the charcoal resistance.

ABSORPTION

When natural gas first comes into contact with charcoal considerable heat is developed, which is the latent heat of vaporization from the condensing vapors. After a few minutes the temperature stops rising, which indi-

FIG. 2A. CHARCOAL QUALITY CURVES
FIG. 2B. 2A YIELD CORRECTED FOR GRAVITY

cates that selection is taking place and the heat of condensation is being used to re-volatilize the highest condensed liquids, which must be eliminated from the final product. Many investigators have ignored this phenomenon, and have stopped when no more heat evolution was noticeable, thinking that the absorption was complete. With gas rich in vapors we have observed a temperature increase of 60 deg. C. in the charcoal due to the latent heat in condensation. This does not mean that the entire body of charcoal increased 60 deg. simultaneously. The heated volume travels in a zone in the direction in which the gas flows. When using a tube of charcoal $\frac{1}{4}$ in. in diameter and 1 ft. in depth and passing rich gas at the rate of 10 ft. per hr., the heated zone is about 2 in. in depth.

The temperature of the charcoal at the beginning of the gas passage is not very important when using gas of low gasoline content. It quickly gains the temperature of the incoming gas. A loss of about 6 per cent in final recovery was experienced when tests were run with the initial temperature of the charcoal 300 deg. C. However, the temperature of the inflowing gas is more important. Fig. 3 shows that the curve of recoverable efficiency is practically a straight line function of the temperature, other things being constant. This curve reaches its zenith at 300 deg. C. Above that there is no recovery at all.

FIG. 3. EFFECT OF TEMPERATURE ON ABSORPTION

TABLE I. HEAT REQUIREMENTS

Weight of gallon gasoline, lb.....	5.5
Saturation of 13 per cent by weight required, lb. of charcoal	42.3
Specific heat of charcoal	0.3
Specific heat of gasoline	0.58
Latent heat of gasoline, B.t.u. per lb.	100
Average b.p of gasoline, deg. F.....	210
Highest temperature of distillation, deg. F.	400

Superheat (400 — 230), deg. F.	170
Superheat required for charcoal ($42.3 \times 0.3 \times 170$).....	2,157
Heat to raise charcoal 60 to 230 deg. F.	170
Heat required to raise charcoal 60 to 230 ($42.3 \times 0.3 \times 170$)	2,157
Distillation of 60 per cent made without superheat.	
Heat required for gasoline distillation (60 to 230 plus latent heat) ($5.5 \times 150 \times 0.58$) + (5.5×100), B.t.u.	1,030
Superheat required for 40 per cent of gasoline distilled..	411
Heat required for first 60 per cent distilled, B.t.u.....	618
Total heat required to raise to temperature of superheat, B.t.u.	2,775
Total amount superheat required, B.t.u.....	2,568
Theoretical amount of heat required, B.t.u.....	5,343
Specific heat superheated steam 15 lb. 400 deg. F.....	0.5
Superheat available per lb. of steam $0.5 \times (400 - 230)$, B.t.u.	85
$2568 \div 85$, lb. of water	30.21
Boiler feed water, deg. F.	200
Boiler heat required, (200 to 400 deg. F.), B.t.u. per lb..	1,089
Total amount boiler heat required (30.21×1089), B.t.u.	32,900
Boiler hp. per gal. gasoline per day	0.045

The rate at which absorption takes place varies according to the richness of the gas mixture. For gas yielding 400 gal. of gasoline per million cubic feet, a rate of 40 cu.ft. per sq.in. of base surface in a 5-ft. column of charcoal is not too high a rate. Above this rate the back pressure due to the resistance of the charcoal itself begins to enter as a factor against higher rates. Fig. 4 presents graphically a series of experiments on rates under these conditions.

The volume of gas to be passed is determined by the nature of the product desired by the operator. If he desires a very volatile product, a low saturation of the charcoal must be had so as not to allow selection to eliminate too much butane, etc. If a staple low volatile product is desired, more gas is passed and the selection is carried as far as desired. This determines the nature of the product and will be discussed later. The volume to be passed to secure the maximum yields for the different grades of charcoal may easily be calculated by the curves given in Fig. 2.

DISTILLATION

After absorption has been completed, it is necessary to expel the condensed vapors from the charcoal. This is done by blowing superheated steam directly through the charcoal. The superheat should be as high as local conditions will allow. There will be a decrease in fuel used per gallon of gasoline recovered, as the temperature of the superheated steam is increased up to the point where the radiation factor of the carrying lines and the efficiency factor of the heater itself become so large as to interfere. Local conditions affect this to a great extent. It will be found, however, that under ordinary conditions 250 deg. C. may be maintained with good results.

The amount of steam required depends upon the percentage of the available heat that is utilized. The charcoal must be heated to 200 deg. C. to dispel the heavier fractions of gasoline. This temperature also insures an active absorbent. The work done is mainly derived from the superheat. The accompanying calculations show that theoretically there are about 5,343 B.t.u. of heat required to produce a gallon of gasoline when the saturation is 13 per cent. Table I shows the heat requirements.

The question is repeatedly asked, "Does this steam distillation injure the charcoal for the other absorptions?"

The steam distillation does not injure the absorptive capacity. In fact, it leaves it in a somewhat better condition than dry heating would conduce. The steam drives out gases and absorbed vapors at a somewhat higher temperature than will permit condensation. The first rush of cooling gas will displace the steam and the first condensation will be of the vapors in the gas. Fig. 5 (solid lines) shows the curves for two samples of charcoal, one of which was being used for the first time for gasoline absorption, the other being taken from the large plant after serving ninety-five absorptions and steam distillations.

A sample of charcoal which had been exposed to the air for a month was divided into two equal portions

FIG. 4. RATE CURVE

One portion was heated to over 500 deg. C. in an open vessel for more than two hours, and the other was treated to 300 deg. C. with superheated steam. The portion treated with superheated steam exhibits an absorption curve which reaches its peak later and shows more retentivity than the dry heated sample. Fig. 5 (dotted lines) shows the curves for this experiment.

CONDENSATION

The gasoline vapors driven from the absorber with the steam may be condensed in any type of condenser. We prefer two water-cooled condensers in series. The cooling water around the first condenser can be circulated just swiftly enough to condense the major portion of steam and allow for its being trapped away without

FIG. 5. EFFECT OF USE ON ACTIVATED CHARCOAL (FULL LINES). EFFECT OF DRY HEAT VS. STEAM ON CHARCOAL (DOTTED LINES)

being cooled much under 100 deg. C. In many localities this condenser may well be an air condenser with enough of the line jacketed to heat the boiler feed water.

The second condenser must be an efficient one. With cooling water at 15 deg. C. or thereabout very efficient condensation will take place at atmospheric pressure.

The condensed gasoline and water flows from the condenser into a separating tank. If it is desired to blend the final product with heavier naphtha to reduce its vapor pressure, that may also be done at this point. We prefer to blend with from 10 to 15 per cent of about 56 deg. B. naphtha.

An examination of the gasoline produced has brought to light the fact that the gravity and vapor tension of this gasoline is less than the gravity and vapor tension of that made from the same gas by either compression or oil absorption. Fig. 6 is a set of curves illustrating this point. There are several reasons for this. Conditions under which the condensation is made affect the character of the final condensate. It has already been noted that the charcoal process gasoline is condensed from a vapor-gas system under atmospheric pressure. This is in direct contrast to the methods of condensation used in the compression or oil absorption processes, where the pressure generally ranges between 90 and 250 lb. When these gasolines are placed in storage or released from compression, evaporation begins to take place immediately and desirable fractions of the gaso-

FIG. 6. COMPARISON OF GASOLINE PRODUCTS

line are carried away mechanically with the escaping undesirable wild vapors.

The method by which the condensation is carried on is also an important factor in determining the character of the condensate. The charcoal process is a batch process. Consecutive distillations of a series of absorbers are made rather than continuous distillations of a single still. This drives out the lighter vapors first and makes possible the addition of the blending naphtha to the fraction that actually needs blending. If there are any very volatile vapors left in the charcoal, they are driven out first by the lowest temperature and do not come into contact with the salable gasoline. By the oil absorption method, which is a continuous process, all fractions are driven out and carried to the compressors together. Here the salable vapors are condensed in the presence of the very volatile vapors under pressure, so that all the salable liquid must be saturated with wild vapors at the temperature and pressure used.

A third explanation for the better quality is found in the method of absorption itself. We have already mentioned selective absorption, which gives clear-cut fractionation controlled by the operator. The wild vapors are practically all re-evaporated into the gas within the absorber itself, thus preventing their presence in the steam-distilled vapors and condensate later on.

Experience has shown that the product from charcoal absorption plants has 3 lb. less vapor tension and 10 deg. less gravity than gasoline made by an oil absorption plant operating on the same gas.

Referring to Fig. 6, we see the results of applying the standard Bureau of Mines distillation test to the gaso-

line produced by the different methods. The initial boiling point of both compression and oil absorption gasoline is from 5 to 10 deg. below the initial boiling point of the charcoal gasoline. The final boiling points and the residue are practically the same. The curves of these distillations show that the big gain in yield is in the recovery of that product boiling between 30 and 70 deg. C., or within the range of the pentanes and hexanes. About 73 per cent of the charcoal absorption gasoline is within this class. Approximately 33 per cent of the compression and 38 per cent of the oil absorption are condensed between these temperatures.

The same series of tests showed that 93 per cent of the charcoal absorption gasoline is recondensed after

TABLE II. WEATHERING TESTS

I—First Pair. Air Temperature 65 Deg. F.

III—Third Pair. Air Temperature 80 Deg. F.								
Time in hours.....	0	2	3	4	5	9	22	25
Oil absorption.....	1,000	965	945	935	922	890	830	828
Charcoal absorption...	1,000	995	988	982	977	960	900	898

the standard Bureau of Mines distillation and approximately 66 per cent of the oil absorption and 63 per cent of the compression material were recovered. None of these samples had been blended before they were tested. The oil absorption sample had been made under a final pressure of 90 lb.

Fig. 7 is a curve showing the application of the Bureau of Mines distillation test to three different fractions of charcoal absorption gasoline. This brings out the fact that the fractionation was very sharp and even the first cut was quite staple.

The weathering losses of gasoline made by the charcoal process are very light. Table II shows three pairs of weathering tests, comparing samples of gasoline taken directly from the blender of a charcoal plant and

FIG. 7. CHARCOAL ABSORPTION GASOLINE CUTS

gasoline taken from the storage tanks of an oil absorption plant, where it has been allowed to weather under about 3 lb. pressure for more than two weeks. All samples were blended with 12½ per cent naphtha 56 deg. Bé. Each pair was kept under the same atmospheric and temperature conditions.

After what has been said about quality, the reader

may infer that the yield is being sacrificed. Such is not the case. A direct comparison between an oil plant and a charcoal plant operating on very lean gas showed that the oil plant averaged around 125 gal. per million cu.ft. of gas and had a weathering loss of 20 to 30 gal. before shipment. The charcoal plant produced an average of 203 gal. of high quality gasoline from this same gas on the same days. The reasons for this wide variation between the two plants are numerous. The problem of bringing every particle of gas into intimate contact with oil capable of absorbing the commercial vapors has always been difficult. Many kinds of baffles and sprays have been tried with varying degrees of success. With an absorber packed with from 8- to 14-mesh charcoal there is no difficulty in getting proper contact for complete extraction.

The absorption of the vapors by a solid medium is governed by conditions entirely different from those governing the absorption by a liquid which depends on reduction of molecular area of the dissolved vapor. It is the capillaries of the charcoal which alter the vapor tension of the absorbed paraffine and make the absorption possible. The degree to which the capillaries are deepened and oxidized free from interfering compounds determines the absorptive capacity of any particular charcoal. However, difference in grades of carbon or any other substance which might be used for the framework of these capillaries is an important factor which must not be overlooked when studying the conditions governing the absorption of gasoline.

The absorption process is actually a modification of the compression process, which consists of concentrating the recoverable vapors before applying the compression. But by the compression method it is possible to condense only a certain part of each fraction included in the gas. This part is determined by the number of fractions present, by the percentage of the different fractions present and by the temperature and pressure employed. It is only a specific application of the partial pressure laws. The addition of air or any gas not condensable at the working pressures means loss in efficiency.

PLANT

Suitable apparatus to practice the charcoal absorption process will include three essential units—viz., a power unit consisting of a boiler equipped with a superheater, an absorber unit consisting of at least three absorbers or charcoal containers, and a condenser unit consisting of cooling coils and a separation and blending tank.

Gasoline Recovery Corp.,
New York City.

Bureau of Standards Has New Standard Samples of Steel and Bronze

A new standard sample of electric steel No. 51, 1.2 per cent carbon, and a new standard sample of cast bronze No. 52 (approximate composition, copper 88 per cent, tin 8 per cent, zinc 2 per cent, lead 1.5 per cent, antimony 0.15 per cent, iron 0.10 per cent and nickel 0.10 per cent) have recently been prepared by the Bureau of Standards and are now ready for distribution with provisional certificates.

Standard sample No. 23a, a renewal of the exhausted sample No. 23, bessemer steel, 0.8 carbon, has also been prepared and is now ready for distribution with a provisional certificate.

The Conversion of Sawdust Into Cattle Feed

BY E. C. SHERRARD*

RECENT investigations carried out at the Forest Products Laboratory indicate that the sawdust of coniferous woods can be converted into a wholesome cattle feed.

The process for preparing such cattle feed depends upon the conversion of part of the wood into sugar by cooking it for about fifteen minutes with a dilute acid under 120 lb. pressure. In this treatment about 20 per cent of the wood is converted into sugar and the remainder rendered more digestible. The sugars are then extracted from the digested dust with hot water, the acid is removed from the resulting solution by neutralization, and the liquor is evaporated under reduced pressure to a thick sirup. The concentrated sugar solution thus obtained is then mixed with the residue left after cooking and the whole is dried to less than 15 per cent moisture content. The finished material is darker than the original sawdust, is very brittle, and contains a larger proportion of fine dust.

FAVORABLE RESULTS AT PRELIMINARY FEEDING TRIAL

A preliminary feeding trial, using a product prepared in this way from Eastern white pine, was conducted by the Wisconsin College of Agriculture with favorable results. Three cows were fed by the reversal method for three periods of four weeks each. In the first and third periods they were given an excellent ration, consisting of alfalfa hay, corn silage and a concentrate mixture of 55 parts of ground barley, 30 parts of wheat bran and 15 parts of linseed meal. In the second period hydrolized sawdust was substituted for part of the barley, 2 lb. of sawdust being fed in place of each pound of barley, as it was not expected that hydrolized sawdust would have as high a feeding value, pound for pound, as barley. The mixture used during the second period contained about 26 per cent of hydrolized sawdust. At no time was any difficulty experienced in getting the cows to clean up this concentrate mixture. The cows maintained their production of milk in the second period as well as in the first and third and showed an appreciable increase in butter fat production. A decided increase in weight was noted during the period in which they were fed the treated sawdust.

NO DEFINITE CONCLUSION YET

While no definite conclusions can be reached from this brief trial, the results do show that cattle may be fed a limited amount of hydrolized sawdust with beneficial results. It should be pointed out that hydrolized sawdust contains only a negligible amount of protein and that it must necessarily be fed in conjunction with other nitrogen-containing materials. In both rations used in this trial plenty of protein was furnished by the other feeds used.

We wish to emphasize the fact that these experiments are preliminary and that as yet the laboratory is not in position to advise as to the commercial application of the process. Further trials will be carried out to furnish additional data on the feeding value and methods of preparation.

Steel Castings of High Strength and Toughness—II

A Chapter From a Forthcoming Book Giving Data on the Improvement to Be Expected After Properly Heat-Treating Steel Castings, With Illustrative Tests on Strong, Tough Castings Which Have Replaced Forgings on Gun Mounts

BY FEDERICO GIOLITTI

Bessemer Medalist

IT WOULD be easy to record a great number of other examples similar to the ones mentioned in the first part of this chapter¹ and illustrates still better the results which may be obtained on steel castings by means of rational normalizing.

Those steel castings already described in an earlier portion of the book would be especially interesting. In these the correct selection of the steel's composition, the special precautions taken during the melting and pouring operations, and the rational application of homogeneity and final heat-treatments would procure articles whose metal would possess physical properties fully comparable to those of the best forged and treated steels.

This is especially interesting in showing how suitably manufactured castings, subjected to a rational heat-treatment, may be substituted in many cases and with great advantage—especially as far as rapidity of manufacture is concerned—for pieces of steel which formerly were necessarily forged and heat-treated. Forged pieces naturally require very tedious and expensive machining operations, in order to be brought to the final form, which in good casting practice is almost entirely obtained by the molding.

Even before 1915 a great deal of study was given to the fabrication and heat-treatment of high strength special steel castings at the steel works of Gio. Ansaldo & Co., obtaining results so satisfactory as to permit castings being used for a great number of gun-carriage

and gunmount parts and of machine parts which had heretofore been fabricated exclusively by tedious machining from heat-treated forgings. The use of these special castings allowed that firm largely to increase its production, and the practice has therefore been greatly extended. Experience with several thousand gun carriages under the severe and exacting use demanded during three years of the great war has fully confirmed the practical advantage and the reliability inherent in the substitution of heat-treated special steel

FIG. 24. MICROSTRUCTURE OF UNTREATED NICKEL STEEL CASTING. $\times 80$

FIG. 23. FRACTURE OF UNTREATED NICKEL STEEL CASTING

castings for steel forgings. This substitution can fortunately be done in a great number of cases where the intensity and nature of the forces to which the mechanical parts must be subjected in service were such as to establish the conviction, held even by the Ansaldo company until a comparatively short time ago, that such substitution was practically impossible.

It is from among these very cases that the following examples will be selected.

CHARACTERISTICS OF MEDIUM HARD NICKEL STEELS

The steels used in the Ansaldo works for the manufacture of such castings are made in the acid open hearth, and the practice has been studied essentially with the end in view of obtaining perfect "deoxidation" of the metal, and the highest possible elimination of "emulsified" non-metallic inclusions which possess an oxidizing power upon the mass of the steel. Another characteristic of the steels in question, due in part to the specific action of the titanium and vanadium used

¹For Part I see CHEM. & MET. ENG., vol. 24, No. 3, Jan. 19, 1921, p. 113.

FIG. 25. TESTS ON ANNEALED NICKEL STEEL CASTING

in their manufacture, is the great "frequency" of the centers of alpha crystallization which form in austenite during allotropic transformation. The great practical importance of this fact has already been set forth by numerous examples, illustrating how the potency and reliability of the heat-treatments are affected.

The steels we are now concerned with belong to the group of the medium hard nickel steels. They are quite brittle when cast and tested prior to any heat-treatment—in fact, averaging the following physical properties:

Tensile strength.....	71,100 to 76,800
Elastic limit.....	54,000 to 61,200
Elongation, per cent.....	3 to 5
Reduction of area, per cent.....	2 to 4
Charpy impact test, kg.-m. per sq.cm.....	1 to 2

A flexure test-piece breaks before even slight bending. The coarsely crystalline structure, typical of these steels as cast, appears still better developed upon the fractured surfaces obtained by bending untreated castings of medium or large dimensions in a press. A typical example of such structures is reproduced in Fig. 23. Fig. 24 shows the normal microstructure of these cast steels before any heat-treatment.

Even simple reheating followed by slow cooling remarkably improves the properties of these steels. Thus, annealing for about three hours at 850 deg. C. imparts variable physical properties within the follow-

ing limits depending upon the composition of the steel and the dimensions of the castings:

Tensile strength.....	71,100 to 78,200
Elastic limit.....	54,000 to 61,200
Elongation, per cent.....	15 to 22
Reduction of area, per cent.....	25 to 35
Impact tensile strength, kg.-m.....	80 to 110
Impact elongation, per cent.....	18 to 27
Transverse impact (Charpy test), kg.-m. per sq.cm.....	4 to 6

A beam subjected to gradual loading usually breaks at an angle of about 90 to 110 deg., as shown in Fig. 25, which also reproduces the appearance of the other fractures. The broken surfaces still show evident traces of the dendrites. Microstructure of the annealed steel is generally as shown (enlargement 60 diameters).

Mild homogeneity heat-treatments such as those studied in the previous chapters modify the structure, which we have often noted as that normal for hypoeutectoid steels of medium carbon content. For instance, annealing followed by rapid cooling in air causes a microstructure of the type reproduced in Fig. 26. A

FIG. 29. FRACTURE OF HEAT-TREATED SPECIAL STEEL CASTING

drawing operation following such an air quenching will give rise to the structure reproduced in Fig. 27. The slight ferrite segregation is entirely normal. As a comparison, Fig. 28 at the same magnification repro-

FIGS. 26 TO 28

Fig. 26. Annealed, air-quenched

Fig. 27. Same as Fig. 26, then drawn

Fig. 28. Air-quenched after forging

FIG. 30. YOKE BEFORE TESTING

duces the structure of the same steel as the one shown in Fig. 27, when quenched in air *after forging*. Evidently the difference between the two microstructures is not remarkable.

APPLICATION OF MULTIPLE HEAT-TREATMENTS

We have previously noted the reasons why a *simple* homogeneity heat-treatment consisting of a single annealing or quenching, even if followed by drawing, does not give results so good as those which can be obtained by more complex treatments. Without going over arguments already discussed at sufficient length, I will only recall that this depends upon the fact that the conditions under which the various phases of a complex treatment take place may be so selected that each of them may develop one of the desired characters up to a certain point without introducing dangerous defects which may eventually accompany the development of that desired property to its maximum. In general such a criterion may be applied only under condition that the successive phases of a complex treatment may be conducted in such a way as to eliminate, or at least sufficiently attenuate, such dangerous effects as may take place in the previous phase.

We have seen numerous examples. Here it is sufficient to remember that even though a preliminary annealing or quenching attended by a very prolonged reheating at a high temperature may give special steels of the type now under consideration a very remarkable homogeneity of chemical composition in the austenitic state, yet on the other hand such practice favors grain growth. Then if the metal has to undergo a slow cooling in the

FIG. 31. YOKE IMMEDIATELY AFTER FRACTURE

successive phases of the treatment, it may easily show Widmanstätten structure, more or less well developed. This case is only another example added to those we have already seen, that the advantages of great uniformity in concentration obtained by means of very energetic homogeneity annealings or quenchings cannot be conveniently exploited in industry, except under condition that further phases of the treatment may eliminate the serious injury which always accompanies the above-mentioned advantages in larger or smaller measure.

It has already been pointed out that in practice the steel may be restored by means of hot work and also by means of certain heat-treatments, consisting essentially of quenchings from relatively low temperatures—such as from within the transformation interval—properly conducted in such a way as to graduate their intensity.

FIG. 32. TRUNNION AFTER BENDING

In these very cases mild quenching as in air, lead, hot oil, boiling water, etc., present the highest practical interest. They permit one to adjust the quenching effect at any desired intensity in the series, starting from the energetic quenchings and ending with quenchings so prolonged as to be comparable to actual annealings. It has already been noted that the special steels lend themselves most favorably to the application of these processes. A correct selection of chemical composition permits a large variation in several different properties: the normal location of $\gamma \rightarrow \alpha$ transformation temperatures, the metastable lowering of these limits, the extreme temperatures of said interval, and, finally, the amount of thermal hysteresis.

Selection of steels possessing strong thermal hysteresis, relatively low transformation points and closely packed centers of ferrite crystallization obviates the necessity of sudden quenchings to preserve the homogeneity obtained at the high temperatures reached in one or more of the phases of the heat-treatment. The main practical consequence of this fact is that the complex heat-treatments may be efficaciously applied to castings of large dimensions and intricate form as well as to simple thin pieces, imparting uniform physical properties to all their parts, even those of varying thickness. Moreover, the application of the desired

FIG. 33. ORIGINAL CONDITION OF SECTOR

heat-treatments is safer because the elimination of quenching avoids the formation of chance quenching cracks. In the great majority of cases the velocities of cooling obtainable with simple air-chilling is sufficient.

EXCEPTIONAL PHYSICAL PROPERTIES OBTAINED

The physical properties which may be obtained by applying the more complete heat-treatments to the cast special steels under discussion range within the limits given below, according to the composition of the metal and to the dimensions of the castings treated. Bending tests under gradual load always reach the maximum deformation into a "U" without showing any crack. If bent flat upon itself it will develop a perfectly localized break.

All fractures have a finely fibrous structure. An illustrative casting when broken by bending under a press presents uniform fibrous fractures from which every trace of crystalline structure has totally dis-

FIG. 34. SECTOR AFTER TWISTING

appeared. For instance, Fig. 29 clearly shows the characteristic dullness or lack of luster and lacerations proper to the broken surfaces of tough metals.

Tensile strength.....	92,500 to 120,900
Elastic limit.....	56,900 to 106,700
Elongation, per cent.....	15 to 30
Reduction of area, per cent.....	40 to 65
Resistance to impact (Charpy test), kg.-m. per sq.cm.....	9 to 15
Impact tensile strength, kg.-m.....	115 to 145
Impact elongation, per cent.....	25 to 35

Even in harder casting the property of withstanding great deformations when cold before breaking is also

FIG. 35. ORIGINAL CONDITION OF TRUNNION

associated with great toughness, as appears from the above physical properties. I would like to emphasize the fact that the castings which I shall now describe were *all of high tensile strength steel*, in which the tenacity was always above 110,000 lb. per sq.in. and the *elastic limit* above 70,000 lb. per sq in. This remark is of the utmost importance properly to appraise the deformations to be described—deformations which could easily be obtained even after simple annealing with mild steel castings whose elastic limit would not be far

FIG. 36. TRUNNION UNDER TEST

FIG. 37. TURNING FROM A HARD CASTING

from 42,000 to 50,000 lb. per sq.in., but which represent exceptional results for hard, high-strength steels possessing the physical properties comparable only to those which can be obtained with forged and heat-treated steels.

A first example is furnished by the piece shown in Fig. 30. A load of 16½ tons was applied by hydraulic press at the ends of the casting while the central boss rested on a single central support. After bending so that the lugs at the ends were lower than the central support not the least crack was found in the piece. On increasing the pressure the piece broke partly through in the manner shown in Fig. 31. Complete fracture was obtained only when the ends were pressed together in actual contact.

A cast trunnion made of high strength heat-treated steel was deformed by pressing against the two ends so as to squeeze them together in the way indicated in Fig. 32. Line AB was originally straight. During this test high external ribs on the under side at C did not develop the least crack, although they were badly stretched.

The sector illustrated in Fig. 33 was placed in a press so that the two points of the arch were squeezed together until it was deformed as shown in Fig. 34. The metal's exceptional toughness in spite of its hardness is demonstrated especially by the absence of fractures even at places where large difference of thickness occur, and where the lines of deformation "accumulated."

Finally, another large trunnion of the same kind of steel and manufactured in the same way is illustrated in Fig. 35 as it appears before cutting the two risers. It was also loaded by a hydraulic press so as to push the ends toward each other. Having reached a condition where the risers were in contact, they were sawed off and the trunnion again placed under the press, as shown in Fig. 36. Localizing the pressure upon the trunnions by means of a block of steel, placed between the hammer and the upper trunnion as shown in the figure, the bending was continued to the point shown without causing the smallest crack in the piece.

In closing these observations regarding castings of heat-treated special steel, it may be mentioned that even during machining such castings present characters of toughness and plasticity which equal and even exceed

those of very mild steel castings or those of the best forged and heat-treated steels. As an example apt to illustrate this fact, I reproduce in Fig. 37 at about one-sixth natural size the appearance of a turning cut from one of the hard castings in question. The figure needs no comment.

Wood-Preserving Industry in 1919

The following statistics on the wood-preserving industry during 1919 are given in a recent Forest Service bulletin issued by the Department of Agriculture:

In 1919 there were 65,556,247 gal. of creosote, 2,412,592 gal. of paving oil, 102,011 gal. of miscellaneous preservatives used in the United States, in addition to 43,483,000 lb. of zinc chloride, the largest quantity of this preservative ever reported by the industry. Of the creosote, 6,493,000 gal. was imported.

Prior to 1917 the plants of this country depended upon foreign manufacturers for approximately 50 per cent of the cresote consumed. Most of this oil came from Germany and England. During the war, however, this supply was cut off, and the plants looked to domestic producers for their supply. Nearly all of the importations in 1919 were from England and Canada.

The material treated consisted of cross-ties, poles, wood blocks, crossarms, construction timbers and miscellaneous material, largely for railroads, mines and telegraph and telephone companies. The total amount of wood subjected to preservative treatment by the 108 plants that were active during 1919 was 139,878,584 cu.ft., or 17,265,694 more than the previous year. About 80 per cent of this wood consisted of railroad cross-ties.

Comparison of Five Different Types of Glue*

For the convenience of those who use glue in wood-working, the Forest Products Laboratory has prepared the following tabular summary of the chief characteristics of five types of glue:

Particular Compared	Animal Glue	Casein Glue	Vegetable Glue	Blood Glue	Liquid Glue
Source	Hides, bones, horns, etc.	Casein from milk	Cassava starch	Dried blood	Animal glue or fish parts
Cost per Lb. 1920	25-42 cents	16-20 cents	10-12 cents	20 cents	\$1-\$5 per gal.
Spread in sq.ft. per lb.	25-35	35-55	35-50	30-100	No data
How mixed	Soaked in water and melted	Mixed cold with rapid stirring	Mixed with alkali and cold or hot water	Mixed cold	No preparation
How applied	Warm with brush or mechanical spreader	Cold with brush or mechanical spreader	Cold with mechanical spreader, not by hand	Cold with brush or mechanical spreader	Cold or warm usually applied by hand
Temperature of press	Cold or with hot cauls	Cold	Cold	Hot	Cold
Strength (in shear test)	High grades stronger than strongest woods	Equal to medium grade animal glue	Equal to medium grade animal glue	High strength in plywood Not used for joint work	Best grades equal to medium grade animal glue
Water resistance	Low	High	Low	High	Low
Chief uses in wood-working	For strong joint work	For water resistant plywood or joint work	For veneer work because of cheapness	For water resistant veneers	For repair work and small articles

* From Technical Notes, Forest Products Laboratory.

Abnormal Behavior of a Weston Standard Cell

BY M. G. MELLON

EXPERIMENTAL work has shown that the Weston standard cell furnishes, in general, a very accurate and satisfactory standard of electromotive force, in having a ready reproducibility, a small temperature coefficient and an electromotive force whose value is suitable for most requirements. Generally these cells are very constant, Hulett and Lipscomb¹ having reported recently the use of certain Weston cells over a period of twelve years. Also most of these cells do not show the disturbing phenomenon of hysteresis. Occasionally however, there is encountered a cell which has not maintained the desired constancy, or one which does not show the expected change of electromotive force with corresponding change of temperature—that is, it exhibits hysteresis.

VARIATIONS SHOWN BY ONE CELL

In some recent work a Weston cell was found to have an abnormally low electromotive force, and to show hysteresis. These variations from the expected results are not new observations. The object of the present note is merely to call attention to them again, because of the belief that some, using such standards, may be inclined to put equal dependence upon the reliability of all Weston standard cells, especially since some reputable dealers advertise that these cells' "accuracy and trustworthiness are beyond question, and with careful handling will remain so for many years."

The Weston cell mentioned was of the unsaturated type and was purchased from the Weston Electrical Instrument Co. in 1917. It was certified at the Weston Laboratory on May 1, 1917, as having an electromotive force of 1.01850 international volts at 25 deg. C., and a temperature coefficient of less than 0.00001 volt per degree C.

CONDITIONS UNDER WHICH TESTS WERE MADE

This cell had been used very little, and never as a working standard, its actual use being a reference cell with which to compare other Weston cells employed through a long series of measurements. In 1917 only a few such comparisons were made, and at that time this cell showed its certified value. No more measurements were made with it until about March, 1919. In the meantime it had been kept in a good apparatus case at the ordinary temperature of the chemical laboratory, and had been subjected to no misuse. At the time of the comparisons in 1919, it no longer agreed with two other closely agreeing, although considerably older, similar Weston cells. Different results were obtained on different days, at approximately the same temperatures; and the values were always at least one millivolt below the certified value.

Accordingly, the cell was sent to the Bureau of Standards for an official test, and the following report was issued for it:

TEST OF UNSATURATED WESTON STANDARD CELL 3,539

The cell was maintained throughout the period of observation within a well insulated box to protect it from abrupt changes in room temperature. The electromotive force in international volts is given by adding the difference in hundred-thousandths of a volt,

tabulated below, to 1.01830 volts, the value adopted by international agreement for the Weston normal cell at 20 deg. C.

DIFFERENCES, HUNDRED-THOUSANDTHS OF A VOLT, FROM 1.01830

Date	International Volts Temperature Deg. C.	Differences	E.M.F.*
April 11	25.0	—116	1.01714
April 12	24.8	—111	1.01719
April 14	23.9	—102	1.01728
April 15	24.5	—123	1.01707
April 16	24.5	—122	1.01708
April 17	24.8	—126	1.01704
April 18	24.4	—117	1.01713
April 21	23.9	—121	1.01709
April 22	24.0	—112	1.01718

*This column was calculated and was not included in the original report.

Because of the abnormal value and of the large amount of hysteresis exhibited with relatively small (and necessarily slow) changes in temperature, we cannot issue our usual certificate certifying this cell to an accuracy of 0.01 per cent.

A marked contrast with the above results was observed in the case of a second, similar cell. This one, purchased in 1915, and certified Oct. 15, 1915, as having an electromotive force of 1.01865 volts at 25 deg., was used at the working standard through three extended series of measurements, the first in 1916, the second in 1917 and the third in 1919. During the last series the cell's electromotive force was practically the same as when first certified.

CONCLUSIONS

The phenomenon of hysteresis described above is not a recent observation in connection with Weston cells, as shown by the work of Dearlove,² Barnes,³ Barnes and Lucas,⁴ and Wolff.⁵ One of the main points to be kept in mind seems to be the uncertainty of knowing which cells may be expected to show such results. After measuring about two hundred cells, Wolff states, as part of his conclusions,

1. That Weston cells can be set up which exhibit extremely little hysteresis in the range 0 to 40, even when subjected to large and rapid temperature variations.

2. That some of the cells showed marked and persistent hysteresis, particularly at lower temperatures.

3. That a similar behavior was found in most of the cells having abnormal values at room temperatures.

The conclusions to be drawn from this note are:

1. The necessity of keeping in mind the fact that all Weston cells do not remain constant over an indefinite time, even though used very little.

2. The advisability of standardizing carefully any Weston cell before employing it for accurate measurements.

3. The probability of obtaining uncertain results using any cell showing such a marked hysteresis, unless its temperature is maintained rigidly constant, as in a carefully regulated thermostat.

Shipments of German Potash

According to figures furnished by the German Potash Syndicate, the sales of potash salts in 1919 reached a total of 4,159,227 metric tons with 812,002 tons of potash. In 1918 the sales amounted to 4,840,934 tons of potash salts with 1,001,664 tons of potash.

The Rise and Development of the Electrolytic Alkali and Chlorine Industry in Europe—III

An Outline of the Electrolytic Cells Employed in the Electrolytic Alkali and Chlorine Industry of the United Kingdom, Germany, Austria, France, Italy, Switzerland, Russia and Belgium*

BY JOHN B. C. KERSHAW

Electrolytic Alkali and Chlorine Industry in France

THE war caused a great increase in the number and capacity of the works for the decomposition of brine by electrolysis in France, since the necessity for producing liquid chlorine on a large scale for the use of the army authorities compelled the extension of many existing electrolytic plants and the erection of some new ones.

According to reliable figures published last year in *La Revue des Produits Chimiques* there were nine works producing liquid chlorine by the electrolytic method in France in 1917, and the aggregate capacity of these plants was 73 tons of gas (or the equivalent of 125 tons of salt decomposed) per twenty-four hours. Only two works were engaged in the electrolytic alkali and chlorine industry in 1914, and this rapid expansion was rendered possible only by the large number of electrochemical and electrometallurgical works which had been established in the Rhone Valley and in the Haute Savoie and French Alps before the war. The water power of this district of southeastern France had in fact been largely exploited in the period 1890-1910; and luckily for France this district of the country was far removed from the zone of actual hostilities and thus escaped the devastation which laid waste the coal-mining districts of the north. Had the Germans managed to penetrate the Rhone Valley, not many of the hydroelectric plants would have escaped destruction.

The number of different cells and processes utilized in these nine electrolytic works are four—namely, the Griesheim-Elektron at Lomotte-Breuil; the Outhenin-Chalandre at Pomblieres St. Marcel, Jarrie, Paimboeuf and Mansieux; the Solvay mercury cell at Saint-Aubans; and a cell and process patented by the Soc. pour l'Industrie Chimique a Bâle, at Montereau, Pont de Claix, Peage de Rousillon and Plan du Var.

The Griesheim Elektron and Solvay mercury cells have been already described; and it is only necessary to describe here the Outhenin-Chalandre and Bâle cells.

THE OUTHENIN-CHALANDRE CELL

This cell was patented in 1893 by the Soc. Outhenin Chalandre Fils & Cie. of Paris, but it has never been operated in the United Kingdom or America, and its use is confined to France and Switzerland. One-third of the liquid chlorine produced in France during the war period was obtained from this type of cell.

The cell is of the diaphragm type, but differs from those previously described in the fact that the diaphragms are constructed in the form of tubes and are arranged in tiers almost horizontally under the bell-shaped hood, which contains the anodes and serves

to collect the liberated chlorine gas. Fig. 16 shows vertical sections of the cell, which is seen to be quite complicated in design and character. A represents the main conductor attachment for the anodes, and M that for the cathodes.

Flat carbon anodes (*aaa*), extend between the diaphragm tubes, as shown by the dotted lines, into the brine contained in the closed anode chamber of the cell; and the current is led away from the interior of the diaphragm tubes (*ccc*) by projecting lugs of the iron cathode bar M; these lugs (*mmm*) extend along the interior of the tubes and serve as the disengagement surface for the hydrogen gas. The caustic

FIG. 16. THE OUTHENIN-CHALANDRE CELL

soda solution which forms on the surface of these cathodes flows by gravity down the interior of the inclined tubes and collects at the bottom of the outer cell, while the chlorine gas is led away from the closed anode chamber or bell by the exit pipe E.

The works at Pomblieres Saint Marcel was started in 1899 by the Société la Volta and was the first operated in France for the electrolytic decomposition of brine. In 1915 it was acquired by the Société d'Electrochimie et d'Electro-Metallurgie of Paris and was greatly extended in order to produce liquid chlorine for war purposes. In 1917 it was producing ten tons of liquid chlorine per day.

The company which now owns this works was origi-

*For Parts I and II see CHEMICAL & METALLURGICAL ENGINEERING, vol. 24, Nos. 2 and 3, pp. 77 and 119.

nally promoted by Gall & Montlaur for the production of electrolytic chlorates at Vallorbes, in Switzerland, with a small water power of 3,000 hp. It has gradually extended its operations until it is now the largest electrochemical and electrometallurgical company in France, controlling over 50,000 kw. of generating plants situated at the following places: St. Michel de Maurienne; St. Avre la Chambre; N. D. de Briançon; Pomblieres St. Marcel; St. Jeoire en Faucigny; Les Clavaux; Pierre Benite; La Barasse; Viellers St. Sepulcre; Vallorbe, and Martigny-Bourg; the last three places in the list being in Switzerland.

THE BASEL TYPE OF CELL

The process and cell of the Soc. pour l'Industrie Chimique a Bâle has been introduced into France during the war, and in 1917 this type of cell was producing nearly one-half of the total output in France (72 tons) of liquid chlorine per day of twenty-four hours. The cell in some respects resembles the Outhenin-Chalandre type of cell, but is rather less complicated in design and is also less costly in upkeep.

This cell is now employed in a large number of electrolytic works in France, Italy and Switzerland, and has been adopted recently by the Soc. Italiana di Elettrochimica of Rome, for its works at Bussi.

The cell is protected by British patent 11,872 of 1913. The following account is based partly on the British patent specifications and partly on a communi-

caustic hydrate formed at the same point and shall carry this hydrate to the surface of the electrolyte and thus remove it from the sphere of secondary chemical and electrolytic reactions.

For this purpose the cathode is placed within a comparatively narrow cathode chamber, constructed of a material permeable to brine, as for example, within a bag having roughly the same form as the cathode and made of a narrow-meshed asbestos fabric. The hydrogen eliminated in this relatively small cathode chamber produces on the surface of the electrolyte a froth consisting of bubbles of hydrogen, the shells of which con-

FIG. 18. MODIFIED FORM OF UPPER PART OF BASEL CELL CATHODE

FIG. 17. GENERAL FEATURES OF THE BASEL CELL TUBE FORM OF CATHODE

cation from the Swiss company received recently by the writer. The chief distinctive feature is what its designers and patentees call a "propulsive cathode," which permits the attainment of a high current capacity in cells covering only a small area and produces at the same time a liquor containing a fairly high percentage of alkali.

The principle of this electrode is that the hydrogen gas evolved at its surface shall act as carrier for the

sist of solution of alkali carried up by the gas. In order to conduct away this froth the upper part of the cathode chamber is contracted so that froth rises in this contracted part and flows over into a suitable receiver in which the hydrogen separates from the cathode liquid that has been carried with it. The cathode may be of various forms, for instance, a rod, in which case the cathode chamber is most suitably formed as a tube; or a plate, in which case the cathode chamber has the form of a narrow box.

The portion of the cathode sheath, or bag, immersed in the electrolyte is permeable and is usually made of coarse asbestos cloth. The upper part, which projects above the electrolyte, is impermeable and is contracted into a narrow iron pipe which serves as conductor for the electric current and is coated with an insulating paint.

GENERAL FEATURES OF THE BASEL TYPE OF CELL

Fig. 17 from the patent specification shows the general features of the tube form of cathode in sectional elevation and indicates the method by which the asbestos sheath, or bag, is attached to the metal top (2). The line marked (4) represents a frame of wire-netting which is used to keep the asbestos cloth extended and also may serve as an extension of the cathode surface. The contracted portion or pipe (5) of the upper part (2) is fixed in a receiving gutter (6). This gutter may also act advantageously as a current conductor for a large number of individual cathode cells, since any desired number of such cells can be attached to it. Within the gutter there may be a hood (7) beneath which the hydrogen collects. It will be obvious that there are many ways of conducting away the cathode current and the hydrogen from the cell. For example, the pipe (5) may be curved over, so as to deliver the solution into a receiver arranged on one side; or as another example, the upper part of the cathode cell can

be formed as shown in Fig. 18. In this case, there extends through the cathode chamber a pipe widened at its upper end to form a funnel and the alkali solution flows down through this pipe.

When such a propulsive cathode, together with a carbon anode, is immersed in a solution of brine and an electric current is passed through it, the current operates in the following manner: In the interior, caustic soda and hydrogen are liberated. The latter carries, in rising through the liquid, the caustic soda solution upward. A froth is formed, consisting of hydrogen bubbles contained in shells of solution of alkali; this froth rises in the contracted iron tube (5) very quickly, and flows over at the top in a continual stream into the receiver (7), in which a separation into hydrogen gas and caustic soda solution at once takes place. The rising hydrogen bubbles and the continual

FIG. 19. BASEL CELL CATHODE UNIT

upward streaming of the electrolyzed liquid act on the brine outside with a strong suction, the result being that over the whole surface of the permeable casing of the cathode a continual stream of fresh electrolyte percolates into the interior, forcing the OH ions (which are usually a source of loss) constantly backward in the direction of the cathode. The rate of upward flow of the cathode liquid and the automatic percolation of fresh brine corresponds to the number of amperes with which the cathode is loaded at any moment. This load may fluctuate within fairly wide limits without having any influence on the efficiency of the cathode, and owing to the permeability of the asbestos bag, the voltage drop is low. As a rule only the resistance of the brine comes into account.

The propulsive cathodes are now manufactured on a large scale to a standard size. Any number can be screwed from below into an iron gutter, and one obtains in this manner the larger cathode unit, shown in Fig. 19. This gutter is fitted to a frame which serves as negative current conductor, and the electric current is carried by this gutter to all the cathodes of the cell. The gutter serves also as receiver for the alkali solution overflowing from each cathode tube. It is covered by a collecting hood for the hydrogen separating from the solution. Gutters and hoods are connected with collecting pipes for the alkali solution and the hydrogen respectively.

As a second component part of the Basel type of cell, in connection with the construction of larger electro-

lyzers, a new form of anode unit is being employed. This consists of a long narrow bell made of some non-conducting material, into which a number of carbon anodes are fixed. In order to obtain as small a distance as possible between the cathodes and the anodes, it has been found advantageous to fix to the bell a bag of the same texture as that employed for the cathodes. The bell has, of course, an opening at the top through which the chlorine rising from the anodes enters the collecting pipe line, by which it is conducted away.

Every electrolyzer is made up of a definite number of the anode and cathode units described above, according to the kw. capacity of the cell and yield of caustic soda and chlorine required. The anodes and cathodes are connected in parallel as shown in Fig. 20. The size of cell employed by the patentees in their own works at Basel produces about 190 kilos of chlorine per twenty-four hours, with the equivalent quantities of NaOH and hydrogen. An electrolyzer having this output requires a depth of rather more than 40 in., and a superficial area of 5 ft. by 10 ft. Usually thirty cells of this size are connected in series.

PRODUCT OF THE BASEL CELL

The concentration of the alkali liquor from the Basel cell varies from 11 to 13 per cent NaOH, or 15 to 17 per cent KOH. The liquor contains some undecomposed chloride, but the amount is not specified. The gas liberated at the anodes tests 98 per cent chlorine, and always less than 2 per cent carbon dioxide, with traces of oxygen. The hydrogen is quite free from impurity. The gases are collected under slight pressure, and any mixing of the gases is absolutely excluded by the design and structure of the cell.

The anode carbons are stated to last three years, a result due to the suppression of OH migration; the asbestos bags incasing the same last, it is claimed, about the same period of time, which is surprising, as

FIG. 20. ANODES AND CATHODE OF BASEL CELL CONNECTED IN PARALLEL

they are in contact with free chlorine. The cathodes and bags are cleaned every six to eight months, since the permeable coatings, especially when employing unpurified chloride solutions, become covered with a thick layer of lime, which lessens the permeability and causes an increase of the voltage. It is unnecessary, however,

to discontinue the working of the cell for cleaning purposes, since each cathode unit and gutter can be lifted out of the containing tank separately, and this can be done also with the single anode bells.

The working of the Basel type of cell is said to be quite simple. The cells are filled up to a certain height with brine, and the electric current is switched on. The propulsive cathodes commence at once their work of circulation, and the caustic alkali solution quickly attains a concentration of 11 to 13 per cent NaOH. A continual supply of fresh brine, corresponding to the quantity of caustic soda solution flowing away, is now fed in at any convenient point; while every propulsive cathode automatically takes the quantity of brine necessary for it, and corresponding to its load of current. The electrolyzers are not heated.

Six electrolytic alkali works in the countries of Central Europe are now employing the Basel type of cell; common salt is being electrolyzed in some of these, and potassium chloride in others.

Electrolytic Alkali and Chlorine Industry in Italy

In Italy, the electrolysis of salt solutions was carried on before the war by three separate companies, two of which employed the Solvay mercury cell, and the third the Outhenin-Chalandre diaphragm cell. The most important undertaking was that located at Caffaro-Falls, and was carried on by the Soc. Elettrochimica del Caffaro. Here the mercury type of cell is employed, with electric power derived from the falls.

The company which operated the diaphragm cell—namely, the Societa Elettrochimica Italiana—has now given up this cell for the Basel type of cell.

The Societa Italiana di Elettrochimica of Rome up to 1918 employed the Outhenin-Chalandre cell, and later a modified form of the Griesheim Elektron cell for its works at Bussi. Owing to the low efficiencies and weak caustic alkali liquors obtained from these types of cell, the company decided early in 1918 to scrap these cells and to adopt the Basel type of electrolyzer.

The new equipment consists of three units of fifty cells, employing a current between 6,000 and 7,000 amp., with an emf. of $3\frac{1}{2}$ to $4\frac{1}{2}$ volts per cell. The new plant is capable of turning out twenty-seven tons of caustic soda per day when the three sets of cells are operated altogether. The consumption of salt is about 1,650 kg. per ton of NaOH, and quadruple-effect evaporators are employed for concentrating the caustic liquors obtained from the cells. The current for each series of cells is provided by a dynamo which generates direct current at 190 to 200 volts. As the waterpower plant at Bussi is capable of generating 6,000 hp., the surplus electric power is at present employed for steam-raising in boilers specially designed for this purpose, and also for the evaporation of the caustic alkali liquors.

The cost of the hp.-yr. at Bussi is stated to be only 55 Italian lire, which at the normal rate of exchange represents \$10.50, whereas coal in Italy today costs from \$20 to \$40 per ton. It is proposed, therefore, to extend the electric heating plant and to employ ultimately 5,000 kw. for these electrically-heated steam-boilers.

The soda solution produced by the cells contains on the average 110 g. NaOH and 200 g. NaCl per liter, with small quantities of chlorate and no hypochlorite. The chlorine contains about 1 per cent CO,

but is fairly concentrated as it issues from the anode compartments of the cell, and therefore it can easily be liquefied in the special plant installed at Bussi for this purpose.

During the war the Societa Italiana di Elettrochimica of Rome was engaged upon the production of poisonous gases and of other materials for military use. The Bussi works, however, is now free from military control, and in addition to manufacturing caustic soda and liquid chlorine the company is producing the following chemicals:

Chlorates of potash and soda; bleaching powder; hydrochloric acid; hypochlorite of soda; compressed hydrogen; tetrachloride of carbon; tetrachloride of tin; magnetite for electrodes; phosphorus and antimony chlorides; benzylchloride; benzoic acid; barium salts, and finally, several electric-furnace products.

Power is obtained from the two rivers Pescara and Tirino, and 50,000 hp. can be developed at this spot when the necessity for further extensions of the works occurs.

Electrolytic Alkali and Chlorine Industry in Switzerland, Italy, Russia and Belgium

The following is a summary of the position of the electrolytic alkali and chlorine industry in Switzerland, Russia and Belgium before the war:

SWITZERLAND

Switzerland possessed two works of this character; that of the Soc. pour l'Industrie Chimique de Bâle at Monthey being the oldest and most important. Here the Basel type of diaphragm cell, which has been described above, was developed and used; and the output of caustic soda, which was only 1,000 tons in 1913, has been increased to over 2,500 tons per annum.

The other works is that of the Soc. Anon. Suisse de l'Industrie Electrochimique Volta, and is located at Chevres, where electric power from the Geneva Municipal Council's generating plant is employed, with the Outhenin-Chalandre type of cell.

RUSSIA

As regards Russia, several electrolytic alkali and chlorine works had been established there before the war by German electrical engineering firms interested in the production and sale of the plant and machinery. The Griesheim Elektron cell and the Solvay mercury cell were the type employed in these Russian works, which were located at Donetz, at Zabkowsice and at Slaviansk, and in all three cases they were operated by steam power.

BELGIUM

Reference may be made to the works of the Belgian Solvay Co., at Jemeppe-sur-Sambre. This works was established in 1898 for operation of the Castner-Kellner mercury cell, and it was here that the improved type of cell which has now been adopted by the English company at Weston-Point was first operated.

The works at Jemeppe before the war operated twenty-three cells of the large type with 1,500 hp. (steam), but since 1914 it has been closed down. In a letter dated February of the present year (1920), from the head office of the company, in Brussels, the managing director of the firm of Solvay et Cie. states that the works at Jemeppe is not yet restarted.

Operating Details of Electric Furnaces

Excerpt From a Report of the Electric Furnace Committee of the Association of Iron and Steel Electrical Engineers Based on a Questionnaire Submitted to Steel Manufacturers
Operating Electric Furnaces

By EDWARD T. MOORE

FROM time to time the question arises as to what limit should be set on transformer primary voltage for electric-furnace service. Transformers having a range from 22,000 to 50 volts are common, and from the transformer standpoint there is hardly any reason why the high voltage should not be doubled, tripled or even quadrupled. However, there are other factors that enter into the situation and in this case are the deciding ones.

As soon as we pass 22,000 volts, the type of oil switch necessary for safely rupturing the current changes to a design that is expensive to install and operate in electric furnace service. Accordingly for 44,000 volts and higher, especially in small units, it is desirable to make the first step from the line voltage to 6,600 volts or 2,300 volts, depending upon the circumstances.

AUTOMATIC CONTROL

The task of keeping the power input to an electric furnace constant within reasonable limits by maintaining the position of several electrodes, with their supporting mechanism and flexible conductors, is not an easy one even when all arcing surfaces are comparatively stable, but when half of the arcing surface is made up of numerous pieces of metal constantly changing under the action of the arcs, the difficulties are considerably increased. From the surface of the molten metal there is a continuous spray of small metallic particles which make it easy to establish the arc before the electrode touches the metal, but with solid metal the electrode must practically come in contact before the arc is struck and then it must be drawn away quickly so as to minimize the current surge. This is the condition met in the first part of melting down a charge of cold steel scrap and is a trying time to all parts of the equipment.

Automatic electrode regulators have been in use commercially in Europe for twenty-five years, and in this country about fifteen years, in both places demonstrating to the user their value in effecting better results and conditions generally.

Compared to the inefficient human machine we have a small relay that follows the impulses continuously and the automatic regulator throws a switch as soon as the change takes place in the circuit, the electrode moving almost instantly to meet the new conditions.

In operating an electric furnace it is desirable to keep all surges within the closest reasonable limits, as these surges have, in practically all cases, a definite bearing on the cost of power, and even when this is not considered, such surges affect other users and frequently cause prejudice against all electric furnaces. Momentary surges are limited by electrical characteristics of the furnace circuit, while the duration of the sustained surge is determined by the electrode control.

A sustained surge tends to carry the current density far above the normal carrying capacity of the electrodes, electrode holders and conductors. As the heating varies directly with the square of the current, a current increase of 50 per cent will increase the heating 125 per cent above normal and accordingly shorten the life of any current-carrying member, especially contact surfaces. The electrode consumption is also increased when the power is permitted to vary over wide ranges and surges tend to cause overheating at weak spots in the electrode with consequent deterioration.

In addition to the important consideration given above there are others of almost equal importance, such as the effect on the quality of the product due to widely varying temperatures at the surface of the metal, effect on the equipment, especially the transformers, due to surge strains, etc.

ARRANGEMENT OF ELECTRICAL APPARATUS

With several notable exceptions, practically all furnace equipments are installed in a straight line—that is, the transformers are located directly behind the furnace and the direction of motion during tilting is directly away from the transformers (Fig. 1). While this method of installation requires somewhat longer flexible leads, there are no side strains to the electrode masts and it is comparatively simple to install apparatus in buildings that were designed for other purposes. As opposed to this arrangement we have the design where the furnace tilts at right angles to the line from the transformers to the furnace (Fig. 2), this arrangement requiring considerably shorter flexible leads but giving considerable side strains to the electrode masts.

Where one polyphase transformer furnishes power to the furnace, the busbar layout is comparatively simple, but with three transformers it becomes much more

FIG. 1. USUAL ARRANGEMENT OF FURNACE EQUIPMENT

complicated. In this connection come the question of using interleaved buses to point where the delta or Y is formed and the flexible leads taken to the transformer, or whether this connection will be made at the transformers and the added inherent reactance accepted as a necessary evil.

The furnace conductors should be so disposed as to avoid unnecessary eddy current losses which increase the reactance and may cause trouble through distortion of the iron work. Care should also be taken that the panels are kept outside of any magnetic loops or fields, as the instruments may be unfavorably affected.

Busbars are usually self-cooled, but an unusual exception is found on two 10-ton furnaces at Buffalo, where the connections from the cables to the electrode holders

chosen for melting that will give the best results for this so-called heavy duty work, while a corresponding value can be chosen for the refining which will give the best results during that important period.

In one installation the greatest power input that could be obtained during the melting down period was 1,800 kw. at 100 volts, while with practically the same furnace design the power input was increased to 3,200 kw. by a moderate voltage increase.

There is a well-defined belief that the high rate of melting obtained by high voltage is detrimental to the quality of the product, especially for tool steel, and this should be carefully investigated. Until the arc shows above the metal, there can be no other objection and possibly the same holds true for the quality of the metal.

FIG. 2. ANOTHER ARRANGEMENT OF FURNACE EQUIPMENT

are thick-walled water-cooled copper pipes. These conductors have given good service during several years' operation.

Flexible cables are necessarily used between the transformer and furnace buses, and a form of insurance is the use of welded terminals that absolutely do away with shutdowns caused by failure of soldered or brazed terminals.

The current density is usually somewhat higher in the cables, approximately 900 to 1,000 amp., than in the bars, which usually run 750 to 850 amp. per sq.in.

On account of the height of the electrode masts, in those cases where the conductors are carried over the tops, a saving in bus copper can be effected by raising the transformer on a pedestal so that the top of the low-voltage leads is on a level with the top of the masts.

VARIABLE OR DUAL VOLTAGE CONTROL

An important subject is the use of double voltage operation for arc furnaces, not only from the standpoint of range of voltages to be used but also the possible detrimental effect of increased rate of melting, obtained by the use of such voltages, on the quality of the metal.

With small furnaces up to one or two tons capacity, except in special cases, there seems to be little reason for going to the expense of installing apparatus for double voltage control. In larger furnaces, however, there seems to be a good reason for using a high voltage during part of the melting period and a lower voltage during the refining period. With a furnace taking 1,500 kva. the voltage applied to the electrode must necessarily be a compromise between a value that will not be so high as to damage the roof and side walls during refining or so low as to lose too much time during melting.

By the use of double voltage control a voltage can be

REACTANCE

The amount of reactance to be used with an electric furnace; its disposition on high-voltage or low-voltage side; the amount of inherent reactance in the transformers; the kind of reactor, iron core or air core, depend upon the type of furnace, the service and local conditions. The reactance stabilizes the arc and determines the limit of short circuit current. The resistance of the leads, electrodes and charge, being small compared to the reactance, can be neglected in this connection.

AMOUNT

Power factor and reactance are intimately connected and considerable harm has been done by advocating too high a power factor.

Public reference was recently made to the unsatisfactory operating characteristics of a 3-ton, three-phase, 1,000 kva. furnace taking power from a 11,000-volt 25-cycle circuit. On account of the low reactance of this equipment, it is common occurrence for the oil switch to open several times during a heat, and as this switch is set at six times normal current, a reactance of approximately 16 per cent is indicated, which should give a power factor of over 98 per cent, a figure unnecessarily high.

If the reactance was doubled, the power factor would be still approximately 95 per cent, while the short circuit current would be decreased from 600 per cent to 320 per cent. If the reactance was still further increased to 43.6, the power factor would still have the excellent value of 90 per cent and the short circuit current would be 229 per cent. This seems to be a desirable value, although if still better protection is desired, such as on a small capacity privately owned plant, a reactance value of 53.7 per cent would give a power factor of 85 per cent and a short circuit current of 190 per cent. These figures are based on values that would be obtained with a reactance having a characteristic of the air core type and would necessarily be altered for iron core reactors and reactors of the compounding type, such as saturated reactors.

A 6-ton, three-phase furnace having transformer capacity of 1,500 kva. on a 60-cycle circuit will have approximately 90 per cent power factor, indicating a reactance of 43.6 per cent, of which about 6 per cent will be in the transformers. The remaining 37.6 reactance, which is principally in the secondary leads, would be reduced to 15.7 per cent on a 25-cycle circuit. The 25-cycle transformer would have a reactance of about 7 per cent, which, added to the 15.7 per cent, would give a total of 22.7 per cent, indicating a power

factor of 97.4 per cent with a corresponding short circuit current of 440 per cent. This indicates that to give the smooth operation of a 90 per cent power factor furnace a 20 per cent reactance should be added to a furnace that normally requires no exterior reactance on a 60-cycle circuit.

Fig. 3 illustrates graphically the relation between reactance and power factor in a circuit. As abscissæ are plotted reactance voltages in percentage of the supply voltage, while the ordinates represent the power factor of the circuit in per cent. Incidentally, the ordinates of this curve also indicate the voltage drop due to resistance in the circuit, or, neglecting the resistance in the transformer and furnace leads, the actual voltage which is obtained across the furnace electrodes in per cent of the supply voltage.

PRIMARY OR SECONDARY

Except on small furnaces, or very high-voltage circuits, the use of external reactance is practically confined to the high-voltage side. In this location it gives additional protection to the transformer against exterior surges and is easier to install on account of the general arrangement of apparatus.

TRANSFORMER REACTANCE

The inherent reactance of a transformer with normal design is from 4 to 7 per cent and this can be increased without much difficulty up to 20 per cent. If additional reactance is to be installed and it comes within this

FIG. 3. RELATION BETWEEN REACTANCE AND POWER FACTOR

value, it appears to be a mistake to keep down the transformer reactance and then increase the installation cost by adding external reactance. This is not necessarily the case, as the equipment will be considerably more flexible if the inherent or uncontrollable reactance is reduced to a minimum and desirable characteristics are obtained by the use of external or controllable reactance. This is especially true in installations using variable voltage control, as the amount of reactance necessary to produce the best results at the high voltage would be excessive and produce undesirable characteristics at the low voltage.

Under ordinary circumstances the choice of reactor lies between the iron core type and the air core type, in some cases there being little to choose from the standpoint of price alone.

The iron core reactor is chiefly used in circuits carrying currents of less than about 50 amp., when a reactance of more than 4 or 5 per cent is required. Under such conditions an air core reactor would require a very large number of turns to give the desired reactance, and the iron core design is considerably more economical.

ELECTRODES

The function of the electrode is to conduct electric energy into the furnace and assist in the production of a proper atmosphere for refining of the metal. Since the cost of electrodes will form approximately 9 per cent

FIG. 4. ELECTRODE

of the total operating expense of a furnace, it will be appreciated that this subject is an important one. This expense will be further increased if excessive breakage is experienced and from the questionnaire below it will be noted this item amounted to an average of 7.7 per cent for carbon electrodes. In addition to this, delays on the furnace due to electrode breakage are costly items and may become prohibitive.

It is believed if more attention was directed toward the proper handling of electrodes by furnace users that excessive breakage would be eliminated and higher economy secured per ton of metal produced. The average consumption of carbon electrodes taken from our questionnaire is 39.9 lb. per ton of metal produced, although there are a number of cases where 30 lb. per ton of metal is an ordinary everyday performance. It would seem as though much improvement could be made toward better electrode economy by better methods of handling and storage of this important material.

One of the large electrode manufacturers has recently published a booklet containing many valuable suggestions for the handling and use of electrodes which we trust will be given wide circulation. With proper handling by the consumer, electrodes should give better service than the average records indicate, for better electrodes are now being made.

Electrodes furnished under this specification are to be amorphous carbon of 14 in. and 17 in. diameter.

Tolerances

Electrodes shall not vary at any point in their diameter over 2 per cent plus or minus from the diameter specified, throughout their entire length, and to be within the following limits:

Nominal Diam., In.	Maximum Diam., In.	Minimum Diam., In.
14	14.28	13.72
17	17.34	16.66

The outside surface of all electrodes to be free of flat spots, bulges, cracks or other irregularities which would interfere with satisfactory operation when placed in the electrode holder of the furnace.

Length

All electrodes furnished hereunder are to be 72 in. long and shall be as straight as possible throughout their length.

No curvature shall exceed $\frac{1}{2}$ in. as determined by using a straight edge which shall engage the electrode for a distance of 9 in. from either end of the electrode. The distance between straight edge and any point on the circumference of the electrode between the 9 in. area and the opposite end shall not exceed the specified variation. See Fig. 4.

Ends

The ends of the electrodes are to be straight and square with the face—that is, a straight edge laid on the end of the electrode would be 90 deg. from a straight edge laid on the face of the electrode for a distance of 9 in. from the end referred to. See Fig. 5.

FIG. 5. END OF ELECTRODE

Threading of Electrodes

Electrodes are to be threaded at each end and symmetrical. The center of the threaded portion is to coincide with the center of the electrode so that when two electrodes are jointed together their edges will not project beyond each other.

Screw Plugs

The screw plugs or nipples are to be made preferably of a material different from the electrode in order that greater tensile strength may be secured.

The threads will be machined to fit "free" so that no binding will take place. They shall not be so "free," however, as to allow end play when the nipple is pulled or pushed while in position, but should be tight enough for good electrical contact and not so tight as to cause vertical cracks in the threads of the electrodes or actual breakage at the ends of the electrodes.

Electrical Resistivity

All electrodes are to have an average specific resistance per inch cube at 20 deg. C. of not more than 0.002 ohm and with no single electrode above 0.0025 ohm.

FIG. 6. APPARATUS TO MEASURE ELECTRICAL RESISTIVITY

The value of the test current to be 300 amp. These measurements may be secured by an apparatus similar to that shown in Fig. 6, although in place of the studded plate contacts, ordinary copper bands may be used. The contact frame connected to the flexible leads of the millivoltmeter should be pressed firmly against electrode and readings taken at various positions along the length and laterally. The average of all readings to be taken as the basis for acceptance or rejection.

Round Electrodes¹

Dia., In.	Area, Sq. In.	Av. Wt. per 60 in. Length, Lb.	Est. Max. Current, Amp.
6	28	99.5	1200
8	50	171.4	2000
10	79	251.4	3000
12	113	359.9	4500
14	154	479.8	6000
16	201	670.0	7000
17	227	687.9	7500
20	314	966.4	1,000
24	452	1508.0	13,500

¹ National Carbon Co.

The figures given for maximum current are approximate and are such as to allow the electrode to operate "black hot." These figures depend on furnace conditions and may vary widely.

Some manufacturers do not believe that electrical resistivity tests of the electrodes is of primary importance to the user, although we feel that the above specification should include such resistivity tests in order to provide data for future discussion.

Tolerance for graphite electrodes should be as follows:

Graphite Electrodes²

Size of Electrode, In.	Tolerance in Diameter, In.	Tolerance in Bowing, In.	Size of Nipple	Threads, per In.
2		$\frac{1}{8}$ on 24 length	$1\frac{1}{2} \times 3$	6
$2\frac{1}{2}$		$\frac{3}{32}$ on 30 length	$1\frac{7}{8} \times 4$	4
3		$\frac{1}{4}$ on 40 length	$1\frac{1}{2} \times 5$	4
4		$\frac{1}{4}$ on 40 length	2×7	4
$5\frac{1}{8}$		$\frac{1}{4}$ on 40 length	2×8	4
6		$\frac{1}{4}$ on 48 length	3×9	3
7	$\frac{1}{8}$ under $\frac{1}{4}$ over	$\frac{1}{4}$ on 48 length	4×9	5
8	$\frac{1}{8}$ under $\frac{1}{4}$ over	$\frac{1}{4}$ on 48 length		
9	$\frac{1}{8}$ under $\frac{1}{4}$ over	$\frac{1}{4}$ on 60 length	$4\frac{1}{2} \times 10$	3
10 x 60	$\frac{1}{8}$ under $\frac{1}{4}$ over	$\frac{1}{4}$ on 60 length	$5\frac{1}{2} \times 11$	3
12 x 60	$\frac{1}{8}$ under $\frac{1}{4}$ over	$\frac{1}{4}$ on 60 length	6×12	2
14 x 60	$\frac{1}{8}$ under $\frac{1}{4}$ over	$\frac{1}{4}$ on 60 length	$7\frac{1}{2} \times 12$	2
		$\frac{1}{4}$ on 60 length	$8\frac{1}{2} \times 14$	2

Bowing to be measured across the concave side from straight edge to electrode at middle. The same method for measuring curvature of carbon electrodes may also be used for graphite, with modifications for the smaller diameters.

Resistivity

The average electrical resistivity of graphite electrodes should be 0.00036 ohm per inch cube, or 0.000914 ohm per cm. cube.

Roof Cooling Rings

As a means of securing better electrode economy more attention should be given to roof cooling rings for the purpose of reducing "spindling" and "wasping." At least one of the members of the committee has experimented extensively with rings of various design, but with no very great improvement in results. Several months ago a new type of roof cooling ring was placed on the market and from investigations made on actual installations very great improvement seems to be indicated.

The gases generated in an electric furnace during operation are only combustible at high temperatures, which means that if they escape to the atmosphere, they are hot enough to burn and in doing so burn up part of the electrode itself and also have a very objectionable effect on the electrode holder. Consequently, nearly all the present-day cooling rings have for their principal object the cooling of the electrode and the cooling of the port holes of the roof.

In the cooling ring under discussion there is obtained the desirable feature of keeping the roof port holes cool, keeping the electrode reasonably cool, and go still further by cooling down the gases, as they leave the furnace, to a temperature at which they will no longer burn when they meet the oxygen of the atmosphere.

While these gases are inside the furnace they are under reducing conditions and have, therefore, only their own sensible heat and no heat generated by the oxidation of combustible constituents. These gases pass, first of all, in between the electrode and the port hole of the roof and then pass through clearance A, Fig. 7, in the cooling ring and into a relatively larger chamber B, which causes the expansion of the gases and thereby giving up a large amount of sensible heat in the gases. This heat is absorbed by the water in the cooling ring. From chamber B they are once more contracted through the small clearance C and are passing to a very large chamber D for a second and much larger expansion. This chamber is surrounded, in the case of graphite electrodes, by a thin inclosed cover E, which in actual

² Acheson Graphite Co.

practice has been found quite sufficient to dissipate the heat given up by these gases, and when they finally pass through the clearance *F*, they are no longer at a temperature sufficiently high to cause them to burn in the atmosphere.

The fact that graphite electrodes can be machined allows the use of a very small clearance at the points *A*, *C* and *F*, which in turn allows a much larger relative expansion into the chambers *B* and *D*, and at one installation, where these cooling rings have been under our close supervision, we have found that even during the periods when carbon is being thrown on to the slag for the purpose of deoxidation, there is not the slightest sign of flames being emitted at the point *F*, and the electrodes themselves do not show the slightest trace of reduction in diameter.

When such economizers are to be used on amorphous carbon electrodes, and especially of the larger sizes and

distance *J* can be altered to suit working conditions. This is desirable from the fact that certain types of electrodes may have a greater variation than others and it may be necessary to increase the capacity of the chamber *D*, whereas for the best type of electrode this distance can be kept down to a minimum and thereby not affect the maximum travel of the electrode jib.

The use of this electrode economizer considerably decreases the amount of electrode consumption, and the port holes in the roof also appear to stand up very much better. This is probably due to the blanketing effect and to the fact that the flames do not rush out through the roof. We have also noticed that there is a much less tendency of the electrodes to taper off and they burn square right down to the point of the arc. This means that the electrode always has the correct carrying capacity at its extremity.

In cases where this type of cooling ring are not used, the air coming in through the furnace doors strikes the white hot electrode and the roof openings act as a chimney, the electrode burning away and penciling off. When the tip of the electrode is thus reduced, it has often to carry very much more current than it has been designed for, and the consequences are that the electrode heats up unduly throughout its length and breakages of electrodes and connecting nipples frequently occur.

Experience so far, while limited, seems to indicate that the above objections are very largely prevented by the use of these economizers.

REFRACTORIES

Silica.—Silica bricks are used as an electric-furnace refractory more than other material for the reason that the melting temperature is very high, being approximately that of platinum, or 1,750 deg. C., and stand up remarkably well up to approximately 1,700 deg. C. They are especially satisfactory for roof brick, as they have an expansion when heated of about 0.25 in. per ft., which permits of maintaining a very flat roof. The bricks are made from quartzite with 95 to 99 per cent silica (SiO_2) and when furnished should contain at least 95 per cent silica in order to stand up.

Silica bricks should be laid in a siliceous mud for mortar—in fact, all refractory bricks should be laid in mortar of the same composition as the brick, to avoid fluxing.

Magnesite.—Magnesite bricks are finding an increasingly large use for those parts of the furnace in direct contact with the charge and for parts exposed to extremely high temperature. The finely powdered magnesite is burned so thoroughly that it is sintered and then forced into shape by the use of very high hydraulic pressure. As it shrinks greatly when heated it is again burned before use and can then be kept in storage without fear of spoiling, for it is not so sensitive to moisture.

Basic mortar must be used with magnesite bricks and the courses should be laid as close as possible, so that even with expansion of the mortar the joints may remain tight and expose very small surfaces of attack to harmful influences. It should be noted that under the influence of other materials at high temperatures certain refractories quickly break down. The following rule must be strictly observed: In the presence of basic influence use basic materials, and with acid influences, use acid materials.

Particular attention should be directed to the building

FIG. 7. COOLING RING

of the makes where the diameters do not run to any regularity, a change is made in the chamber *D* of the economizer. The gases there, instead of being all allowed to pass through the clearance *F*, pass through perforated plates *H* on the outer wall of the cover *E*, and by keeping these perforations as small as practical, the plates *H* will act on the principle of the metallic gauze used in Davy miners' lamps, in which it is well known that the heated gases of combustion from the lamp are cooled to such an extent that the lamp can be very safely used in the dangerous explosive gases of coal mines.

The cover *E* will be made adjustable, so that the

of the side walls in a furnace so as not to have them too steep, else it will be very difficult to repair or patch up disintegrated portions.

Very great success has been secured with dolomite in making bottoms for furnaces. It is a limestone containing a considerable proportion of magnesite and when burned forms a valuable refractory, but should be mixed with pitch or tar before ramming into the furnace and used as soon as possible, because of its lime content ($\text{CaCO}_3\text{MgCO}_3$) it readily absorbs moisture from the air and falls to powder.

BRASS FURNACES

The reason for the rapid increase in the use of the electric furnace in the conservative brass industry and for melting other non-ferrous metals and alloys is the production of a uniform metal by eliminating or minimizing operators' errors under the trying conditions of fumes and high temperatures met while handling crucibles, eliminating contamination from furnace gases, preventing loss of volatile constituents through uneven heating and, in general, making a uniform product by superior heat control. Also as we are mixing two or more metals having different specific gravities and melting points, it is necessary to have efficient stirring, and this is accomplished both electrically and mechanically.

Furnaces may be broadly divided into those in which the heat is generated in the metal, those in which the heat is generated at the surface of the metal and those in which the heat is generated externally to the metal and radiated or otherwise transferred to it.

In the first group we have the induction furnace for normal frequencies as exploited by the Ajax Metals Co., of which there are many in successful operation. These furnaces are very efficient and are best adapted to large plants where one or more furnaces can be used continuously on the same class of metal. In small plants, or where several heats are to be made of one alloy and then another composition is required, this type of furnace is at a serious disadvantage, as they are usually started with a charge of molten metal. Intermittent operation of this furnace also has a detrimental effect on the lining and it is practically limited to continuous operation.

Another type that is passing through the experimental stage operates on the induction principle and is designed to take power at 9,000 cycles or higher. The equipment is very simple from all standpoints except the power equipment, which has been the chief obstacle in the development of equipments of commercial capacity. This furnace can melt or heat any metal to any reasonable temperature and should be of great value when fully developed.

In the second group we have furnaces where the current passes from the electrode to the metal, and it is necessary in this case to reduce the voltage drop between the electrode and the metal to such a value as will practically eliminate arcing. This is necessary on account of the intense heat developed by an arc in the surface of the metal, causing tremendous vaporizing losses which could not be tolerated.

The third class includes arc furnaces where the heat is generated above the metal and radiated to it and the refractory walls. By oscillating or rotating the furnace shell, the metal is mechanically stirred and absorbs heat from the refractories, thus tending to keep them at practically uniform temperature.

Other types of furnaces using exterior heating are resistance furnaces where the heat is generated in resistors and radiated or conducted to the metal. The latter types have neither electrical nor mechanical stirring and must depend upon mechanical rabbling together with slight stirring due to heating effect through the lining. Various other types are under development, but they are not of sufficient commercial importance to warrant consideration here.

The consumption of electric energy varies from a reported figure of 174 kw.-hr. per ton in continuous operation on induction furnaces up to 240-500 kw.-hr. for intermittent operation on arc and resistance types.

CONCLUSION

The data secured from the questionnaire indicate very conclusively that the greatest need at present is for better electrode economy, which means watching closely the handling, storing in a warm dry location and proper joining of electrodes. The improvement of the present largely used roof cooling ring will have a big effect on electrode consumption.

Lack of tensile strength seems to be one of the difficulties of electrode trouble caused by the lines of cleavage of the calcined anthracite coal being in a vertical as well as horizontal direction, it being impossible at present to build an electrode where all the cleavage lines are horizontal. Recently some amorphous carbon electrodes have been made with a hard bonding material which increases the density very materially. While their use has been over a period of only six months, preliminary reports indicate a greatly reduced breakage. If some method of placing the material of electrodes in a position to present its lines of cleavage at the best advantage were devised, no doubt practically all breakage could be eliminated.

One of the chief sources of difficulty in furnace operation is delays due to handling material to and from the furnace. This difficulty increases as the number of installed furnaces becomes larger. The practice of bringing the scrap on the surface floor from the rear and adjacent to the furnace in small cars on tracks and using traveling cranes entirely for handling the steel from the furnace is certainly desirable and conducive to reduced delays.

The present method of charging scrap into a furnace by shoveling and peeling means a delay of at least one-half hour. Using an automatic charging machine will reduce the time of charging materially, but it will not be able to place the scrap as uniformly as may be done by hand; therefore, during melting the power fluctuations will be greater. With hand charging, the scrap can be placed uniformly and a greater tonnage treated.

Although considerable work has been done toward perfecting the electric furnace and its accessories, there is opportunity yet for very extensive research, and we believe the necessary results will be forthcoming in the very near future.

Changes in Regulation 60 on Alcohol

A supplement to Regulation 60 relative to dealing in, transportation and use of tax-paid industrial alcohol in original stamped packages only has recently been issued from the Office of Commissioner of Internal Revenue.

Federal prohibition directors and others concerned may obtain the detailed information by writing to the Treasury Department, Office of Commissioner of Internal Revenue, Washington, D. C.

Ternary Brasses

AS LONG ago as 1905, Léon Guillet published¹ some investigations on special brasses, in which he was led to the conception of "fictitious compositions" in an attempt to systematize the results. Thus when adding various percentages of tin to a 60:40 brass, he found that the microscopic appearance of three brasses when slowly cooled were quite similar and consisted of light secondary crystals of γ in a dark matrix of β . These were² 54:40:6, 60:30:10, and 46:54. Up to 10 per cent, tin evidently entered into solid solution, and acted like zinc, but with a potency several times as great. In other words, both of these tin-brasses might be thought of as having a "fictitious" composition of 46 Cu, 54 Zn. From the standpoint of the equilibrium diagram, Fig. 1, tin apparently moves points a_1 , b_1 and c_1 to the left.

Similarly, when studying the ordinary physical properties, tin additions up to 2.2 per cent increase the strength and hardness of 60:40 brass. Ductility and

FIG. 1. EQUILIBRIUM DIAGRAM FOR COPPER-ZINC ALLOYS
After Gulliver, "Metallic Alloys," p. 267

shock strength is badly affected when tin is above 1 per cent. All of these changes are in the same direction as they occur when the copper content of the brass is lowered.

Further detailed studies along these lines were published in the following year,³ paying especial attention to the effect of aluminum, which appears to be especially powerful in displacing sidewise the properties vs. composition curves. As many as nine other metals have been studied as to their effect on brass. Guillet states the general conclusions that on the introduction of a small amount of third metal to a Cu:Zn alloy it enters into solution with the normal constituents up to saturation, but by so doing it brings the ternary alloy into a state microscopically equivalent to a binary Cu:Zn alloy of fictitious composition, and physically more nearly like the latter than the brass containing Cu:Zn in the ratio actually present. Physical properties of the fictitious binary brass, when compared to the same properties of an actual brass of the same composition, are of course modified by the inherent properties of the third element. Beyond the saturation point a special constituent appears, and the above generalization no longer holds.

For example, if a 70:30 brass has 2 per cent aluminum substituted for 2 per cent zinc, the actual composition would analyze 70:28:2. Now suppose 1 per cent Al plays the same rôle as 6 per cent Zn. The proportions of copper and equivalent zinc may then be stated as 70 parts copper and 40 parts zinc, which figured to 100 gives an analysis of 63.6 per cent Cu and 36.4 per cent Zn, the "fictitious composition" for a 70:28:2 aluminum brass.

MATHEMATICAL STATEMENT

Such a relation may be stated mathematically: "A body added to a brass possesses a coefficient of equivalence t when 1 per cent of this body will enter solid solution and replace t per cent of zinc, the proportions thus obtained being figured to 100."

In symbols, let A be the real percentage of copper, B the real percentage of zinc and q the real percentage of the third element.

Then

$$A + B + q = 100$$

Also let A' be the fictitious percentage of copper, B' the fictitious percentage of zinc and t the coefficient of equivalence.

Then

$$A' + B' = 100$$

and

$$B' = \frac{B + tq}{A + (B + tq)} = 100$$

Figuring explicit functions for A' , q and t from these expressions one gets

$$A' = \frac{100 A}{100 + q(t - 1)} \quad \text{for figuring the fictitious composition of a given ternary brass.}$$

$$q = \frac{100}{t - 1} \left(\frac{A - A'}{A'} \right) \quad \text{for figuring the quantity of third metal to be added to A brass to approximate the properties of A' brass.}$$

$$t = 1 + \frac{100}{q} \left(\frac{A - A'}{A'} \right) \quad \text{for figuring the coefficient of equivalence of a metal of which } q \text{ per cent changes alloy A to approximately that of A'.$$

DETAILED STUDY OF ALUMINUM BRASSES

As noted above, the second publication gives the details of an extensive study on aluminum brasses to illustrate and verify the general ideas thus expressed. In the first place the coefficient of equivalence was determined approximately, then verified by synthesis of a typical brass, and finally the mechanical properties were studied—tensile strength, Frémont impact, Brinell hardness, and forgeability.

Varying amounts of aluminum were added to a 60:40 brass, the resulting alloy analyzed chemically, and examined micrographically. From such data t can be calculated. Some results follow:

Chemical Analysis		Microscopic Analysis	t
Copper	Aluminum	Copper ⁴	Calculated
59.6	0.3	59	6.1
59.9	0.8	57.5	6.2
59.6	2.9	50.5 to 54.75	7.2 to 4.1
Average about.....			6.0

Given this value of t , it was verified by trying to pro-

¹Revue de Métallurgie, 1905, vol. 2, p. 97.

²Compositions give percentage of copper first, then zinc, and lastly of the third metal.

³"General Study of Ternary Brasses," by L. Guillet, Revue de Métallurgie, 1906, vol. 3, p. 243.

⁴The microscopic appearance of the ternary alloy approximated to within plus or minus $\frac{1}{2}$ per cent the appearance of a binary alloy with copper as indicated. In other words, this table might be headed A' .

duce ternary alloys whose compositions were equivalent to certain well defined microscopic appearances. Thus:

Given Copper	Figured Al	Required A'	
70	2.22	63	β constituent first appears
60	1.92	54.75	Traces of α constituent
60	3.76	50.5	A little γ is seen

As the result of many trials the following data were determined by chemical and micrographical analysis:

A	q	A'	t Calculated
70.3	2.3	63	6.04
59.8	1.65	55	6.27
60.4	4.7	50	5.42

Average..... 5.91

which was regarded as checking the round number 6.0 sufficiently well.

Higher aluminum alloys were also analyzed:

A	q	A'	Calculated t
68.47	4.50	56.0	5.94
68.49	5.60	53.0	6.21
78.73	7.14	57.0	6.33

A third series of tests varied the amount of copper in an attempt to retain the same structure.

Aimed at			Analyzed			
A	q	A'	A	q	A' Found	A' Calculated ⁵
70	4.4	57.3	69.6	4.95	56	55.7
65	2.7	57.3	66.4	3.0	58	57.7
60	0.95	57.3	59.9	1.17	56.5	56.5

A great many test-bars were broken in an attempt to correlate and systematize the observed data. From these results the following trio are typical.

Cu	Al	Fictitious Cu	Ultimate	Elastic Limit	Elonga- tion	Contraction	Impact Strength	Hard- ness
64.73	1.64	58.8	51,200	17,600	38.0	40.7	10	69
57.96			50,600	9,400	44.0	49.9	13	73
64.7			30,300	5,700	55.0	53.8	17	39

Evidently the physical properties of the ternary brass are more nearly those of the simple brass of fictitious composition than that with the same percentage of copper. From all these tests it is plain that in industrial

FIGS. 2 AND 3. GRAPH SHOWING RELATIONSHIP BETWEEN AMOUNT OF THIRD METAL AND FICTITIOUS COMPOSITION

brasses (with greater than 55 per cent copper) aluminum increases the breaking strength and elastic limit, but if added even in small quantities to 58 per cent copper brasses it may render the product worthless by bringing in the brittle γ solution.

⁵On the basis that $t = 6.0$.

FIG. 4. TERNARY DIAGRAM FOR ALUMINUM BRASSES

GRAPHIC REPRESENTATION

Equation $A' = \frac{100A}{100 + q(t-1)}$ if plotted in A' and q will assume the form of an equilateral hyperbola asymptotic to horizontal axis (q) and a parallel to the A' axis at $q = -\frac{100}{t-1}$. There are two cases, of course, as shown in Figs. 2 and 3, the first where t is greater than 1, and the second where it is less than 1. If $q = 0$, $A' = A$, and in the former case as q increases A' becomes less than the real copper analysis. If t is less than 1 it is evidently useless to add a greater quantity of the third element than $-\frac{100}{t-1}$; however, one or more special constituents due to supersaturation would ordinarily intervene long before.

A ternary diagram for aluminum sketched on these principles is given in Fig. 4. The asymptote is at -20 .

RESULTS IN VARIOUS ALLOYS

Similar detailed studies were made by the author on many addition metals; the details can be consulted in *Revue de Métallurgie*, 1906, vol. 3, p. 243. It must suffice here to tabulate the results obtained, together with notes as to the limits of usefulness of Guillet's generalization—that is, the analysis where a special constituent appears in the alloy. Nickel brasses have further been studied in great detail, and have been briefly reported in 1913⁶ and more fully in 1920. Extensive summaries of these papers will be presented in subsequent issues of *CHEMICAL & METALLURGICAL ENGINEERING*.

TABLE OF RESULTS

Element		Special Constituent Appears =
Al.....	6.0	7.1% in 69% Cu
Mn.....	0.5	8% in 60% Cu
Fe.....	0.9	?
Sn.....	2.0	0.7 up to 63% Cu, 9% at pure Cu
Pb.....	1.0	0.9% in all brasses
Si.....	10.0	1.4% up to 63%, 2.0% @ 90%
Mg.....	2.0	0.25%
Sb.....	?	0.4%
Cd.....	1.0	0.9% (much like lead)
Ni ⁶	1.3	None
Co.....	Variable ⁷	4.3

Such studies should simplify the ideas covering special brasses, and make their fabrication the more dependent upon reason—especially for the forgeable alloys. Required physical properties may therefore be reached by simple analyses, replacing highly expensive and delicately worked alloys of high complexity.

⁷*Revue de Métallurgie*, 1920, p. 494.

H. Foster Bain Becomes Director, Bureau of Mines

IN ASSUMING the directorship of the Bureau of Mines left vacant by the resignation of Dr. Cottrell to become chairman of the Division of Chemistry and Chemical Technology of the National Research Council, H. Foster Bain brings to his new duties a full realization of the importance of the chemical work of the bureau. As a matter of fact, one of the first big questions which came before him was in regard to this phase of the bureau's activities. The Committee on Appropriations had just reported out the sundry civil bill, omitting the items which had been requested by the bureau for extended work in the interest of the chemical industry. That made it necessary to lay plans immediately for renewed efforts in behalf of the industry which has taken on such increased importance since the outbreak of the war.

Mr. Bain was born at Seymour, Ind. After his graduation from Moore's Hill College, Indiana, in 1890, he spent two years at Johns Hopkins University and later received his doctor's degree from the University of Chicago. He was educated and trained as a geologist and mining engineer. He was one of Herbert Hoover's assistants in London on the Belgian relief work during the war. From 1909 to 1915 he was the editor of the *Mining and Scientific Press* of San Francisco, Cal., and later the editor of the *Mining Magazine* of London, England. He made some important mining investigations in south and central Africa and later undertook similar investigations in China. At one time he was a mine operator in Colorado and once was connected with the U. S. Geological Survey. Subsequently, he was the first director of the Geological Survey of Illinois.

In addition to Mr. Bain's contact with British mining affairs, during his residence in England as editor of the *Mining Magazine*, he has been engaged in consulting work in the Rand, the Belgian Kongo and other mining regions of Africa. He also has had considerable experience in the Far East. During the two-year trip from which he has just returned he made mining examinations in ten Oriental countries.

While Mr. Bain is more widely known for his work in geology and as a mining engineer, he has given far more attention to chemistry than has the average consulting mining engineer. While at Johns Hopkins University he received special training in chemistry under Prof. H. N. Morse in addition to the chemical work connected with the regular courses in metallurgy. At Cripple

Creek in 1901 he conducted a series of experiments on the cyanidation of Cripple Creek ores. He was among the first to attempt the heating of solutions. This practice has since developed some importance in connection with certain ores. At a later date he did extensive work on South Dakota ores in connection with the controversies which have arisen over patents covering cyanidation and concentration. Mr. Bain points to these early efforts as an indication of the relatively larger amount of duplication which took place before the work of the Federal Government provided a clearing house which enables all concerned to have the benefits of current developments, thereby speeding the perfection of improved processes. In connection with Mr. Bain's South Dakota work, it later developed that practically the same problems were being worked out at the Homestake Mine.

Just at present Mr. Bain is carefully considering the question of the character of research which should be undertaken by the Bureau of Mines. He is weighing the arguments advanced by manufacturers that the Government's research too frequently encroaches upon a field which properly belongs to private industry and believes that a definite line can be drawn where there will be no such encroachment. His study of the subject, however, has not reached the point where he is prepared to make an announcement of the bureau's future policy in that regard.

An incident in Mr. Bain's earlier experience brought home the fact that human relations as well as applied science are involved in every engineering project. After receiving his doctor's degree he sought employment as a shift boss in a mine with the idea of gaining first-hand experience in that phase of practical operation. He took charge of a gold-silver operation known as the Franklin mine in Clearcreek County, Colorado. The mine labor employed was Italian. Some friction had arisen as to the selection of a night shift boss, the first Sunday after Mr. Bain's arrival. The affair had given rise to a serious fistic encounter which kept Mr. Bain busy during his day of rest in negotiations with the keeper of the jail and the physician in charge of the hospital. This was followed a few days later by another phase of the feud in which work on the property was stopped by a concealed rifleman who amused himself by making the mine mouth his target. Finally, however, Mr. Bain got things running smoothly as far as open hostilities were concerned, but he learned that mining involves a great deal more than a knowledge of engineering and geology. In fact his first task on that job was to teach the men to use hammer drills, which were just coming into use at that time.

Dyes and Coal-Tar Chemicals in 1919

The Census of Dyes and Coal-Tar Chemicals for 1919, which has been issued recently by the Tariff Commission as Tariff Information Series 22, is indeed a report of progress in these essential industries.¹ Outstanding features of the census have been given in the preliminary summary by Dr. Grinnell Jones, published in *CHEM. & MET.*, vol. 23, p. 661, Oct. 6, 1920.

INTERMEDIATES

The decrease in the production of intermediates from 357,662,251 lb. in 1918 to 177,362,426 lb. in 1919 can be traced almost entirely to the diminished demand for products used primarily for explosives. The most spectacular case is that of phenol, which dropped from 106,794,277 lb. in 1918 to 1,543,659 lb. in 1919. In this report intermediates are grouped as benzene, toluene, xylene, naphthalene, anthracene and carbazole compounds, each group being subdivided whenever possible into classes of derivatives, such as halogen, nitro, amino, sulphonic acid, hydroxyl, etc. It is interesting to note that the production of anthraquinone in 1919 (294,260 lb.) exceeded the production of anthracene (purity of 25 per cent or over) in 1918 (225,552 lb.). The corresponding figure for anthracene in 1919 is 1,381,944 lb.

Another helpful innovation in this section is a list of intermediates used in the production of developed or coupled dyes directly on the fiber and in printing. Many of these compounds were sold before the war under trade names, such as Developer J and Reserve Salt O, and this list gives the chemical name corresponding to the trade name in the hope that customers will be able to obtain the materials more reasonably and that it will also help intermediate makers to supply those not yet made in this country.

DYES

Besides the itemized table showing a production of 63,402,194 lb. of dyes, valued at \$67,598,855, there is

FIG. 1—PRODUCTION OF DYES—1917—1918—1919
COMPARED WITH IMPORTS—1914.
BY CLASSES

included a comparison of 1914 imports with the production of dyes by classes in 1917-1919 inclusive. This is shown graphically in Fig. 1. It will be noted that the

classification is based upon the method of application on the fiber.

One hundred and ninety-one firms reported a total of 24,736 employees engaged in the manufacture of coal-tar products, of which 2,605, or 10.5 per cent, were chemists or engineers. This is probably a larger proportion of technically-trained men than will be found in any other important manufacturing industry in the United States. The group of employees receiving \$40 or more per week included 57.4 per cent of the technical men, but only 12.7 per cent of those without technical training. Corresponding figures for \$75 or more are 12.67 and 0.14 per cent respectively.

RESEARCH WORK

Of the total of 214 firms, 65 had separately organized research laboratories for the solution of technical problems in the manufacture of their products and for the discovery of new products. During 1919 the net operating expenses of these research laboratories, together with the cost of research work done in laboratories not separately organized for research, was \$4,274,247. This includes salaries, apparatus and materials, after deducting the value of salable products made in research laboratories. This figure is probably an understatement of the real cost of experimental work, since it does not include in all cases work of this nature done as a part of manufacturing operations and is not shown on the books of the companies as a charge against research.

CONDITIONS IN OTHER COUNTRIES

Beginning with February, 1920, detailed statements of one-quarter of the monthly production of every dye in each German factory were made to Reparations Commission, as required by the peace treaty, Annex VI, Part II. A classified summary of these reports from February to October, 1920, is published in this report by permission of the Department of State. A progressive increase is shown in each succeeding month to a maximum of 3,026,247 lb. in August, which indicates a total output of over 12,000,000 lb. per month. The rate of production from July to October inclusive is only about one-third of Germany's pre-war output.

Conditions in England, Switzerland, France and Japan are also briefly reviewed.

IMPORT STATISTICS

Information as to the importation of individual dyes is given in Part III of the report, which is a census of dyes imported into the United States during the fiscal year 1920. The Schultz and Julius number is given wherever possible, together with the name of the manufacturer. The companies listed include thirteen German, six English, four Swiss, two Dutch, one French and one Belgian. The imports total 3,501,147 lb., with an invoice value of \$4,458,109.

The names of 171 firms which manufactured coal-tar products during 1919 will be found in the appendix to this report. Coke-oven plants and gas houses which reported to the Geological Survey are not included.

¹Copies of this report may be obtained for 20c. from the Superintendent of Documents, Government Printing Office, Washington, D. C.

Chemical Tariff Schedule Under Consideration

Schedule A, that portion of the tariff which includes such chemicals, oils and paints as are not on the free list, was the subject of hearings on Jan. 6, 7 and 8. Judging from the attitude of the committee during those hearings and those which have followed, it seems apparent that the intention is to frame promptly a tariff bill which will provide rather arbitrary rates due to inability to ascertain accurately the costs of production abroad and to the difficulty of forecasting the economic situation either at home or abroad. The bill probably will be enacted with a full understanding that it is to be amended frequently as conditions may change.

DOMESTIC MARKET VALUE CONSIDERED AS BASIS

There is very decided sentiment in favor of ad valorem duties to be based on the market value of the commodity in the United States. Apparently the majority of the committee would like to see this plan tried. It is admitted, however, that many obstacles must be surmounted to make the plan effective. To start with, it will be necessary to scrap the intricate governmental machinery which has been built up through a long period of years for making valuations in foreign countries. There is objection on the ground that it will be unwise to disband such an organization in order to experiment with American valuations. Another difficulty arises in the fact that a large proportion of imports are specialties which are not manufactured in this country and on which it will be difficult to fix a fair American valuation.

DATA ON FOREIGN PRODUCTION COSTS UNRELIABLE

Those who have testified before the committee have had a great deal to say about cost of production abroad and most witnesses, in response to questions from the Democratic side of the committee, have stated that all they want in the way of tariff is a rate which will equalize the costs of production. In the face of cross-examination, it has developed that little accurate information is available as to costs of production abroad. The question is further complicated by the exchange situation and from the fact that currency has one value in foreign exchange and entirely another value when it comes to purchasing labor within the country of issue. Moreover, foreign costs are undergoing violent fluctuations.

FURTHER DEPRESSION MUST BE AVOIDED

Republican members of Congress are outspoken in their desire that great caution be used in framing this tariff law. If excesses are permitted to creep in and the rates are made too high, the effect of the law in increasing prices to consumers in the time of depression will react to the disadvantage of the party and the protective tariff idea. It is recognized that at present there are a large number of influences at work tending toward depression. With a new tariff act in the spot-light, it probably would be blamed for a condition for which it could be only partly responsible.

CONSUMING INTERESTS WELL ORGANIZED

Never before when a tariff bill was in the making have the consuming interests been so well organized. The successful outcome of the fight made by some of the textile interests on the dye bill is an indication of the skill with which opposition to tariff can be brought to play on such commodities as are used by powerful aggregations of consumers.

The consensus of opinion among those who were in attendance at the hearings on the chemical schedule is that the case was splendidly presented to the committee. There is abundant evidence that the committee is particularly sympathetic with the necessity for protecting the chemical industries. It is understood that the chief point of Democratic attack will be on other schedules. It is regarded as practically certain, however, that there will be some material reductions in the rate of duty requested by domestic manufacturers.

STATEMENT OF MANUFACTURING CHEMISTS ASSOCIATION

Henry Howard of the Grasselli Chemical Co. opened the hearings on the chemical schedule with a general statement for the Manufacturing Chemists Association. He pointed out that the manufacturing chemists appearing were confining themselves to articles not covered by the pending dye bill. He pointed out in the beginning of his statement that the problem is not alone one of depreciated foreign currency or of low foreign exchange, but is one of low wages. He said that German labor now costs half what it did before the war. He said that the development of the chemical industry is the best index of the progress of civilization in a country. He called attention to the fact that chemical development is predicated on continued systematic research carried out at great expense by the most highly trained experts obtainable. This sort of work is possible only when the industry is in a prosperous condition, because a number of years usually are required before there is any cash return from the products of research.

SPECIFIC VS. AD VALOREM

Mr. Howard made a plea for specific rates rather than ad valorem rates, where the substitution is possible, so as to simplify the administration of the act. He called attention to the fact, however, that in many cases two or more specific rates should be provided. He used this illustration:

Paragraph 73 of the 1909 act provided: "Sulphide of soda, containing not more than 35 per centum of sulphide of soda, $\frac{3}{4}$ of 1 cent per lb.; sulphide of soda concentrated or containing more than 35 per centum of sulphide of soda, $\frac{3}{4}$ of 1 per cent per lb." In the act of 1913 this dual classification was abandoned and a flat rate of $\frac{1}{4}$ of 1 cent per lb. substituted, with the result that only the concentrated product, 1 lb. of which was equal to 2 lb. of the crystals, was imported at a rate designed for the crystal or unconcentrated variety. This concrete instance is given as being typical of a great many and shows the advisability of providing two or more specific rates in all cases where it is possible to substitute a more concentrated or more valuable product for the one in common use at the time the tariff is written.

NEED FOR ANTI-DUMPING LEGISLATION

Mr. Howard emphasized the necessity for providing anti-dumping legislation. In that connection he said:

The association notes with approval the passage of the Fordney anti-dumping bill H.R. 10918 through the House of Representatives, Sixty-sixth Congress, second session, and the introduction of the Smoot anti-dumping bill in the Senate, as indicative of the intent of Congress to legislate on this most important matter, and most respectfully urges upon the Committee on Ways and Means that the next tariff act contain adequate and complete provisions along the lines of the Fordney and Smoot bills, bearing in mind that in our best judgment, no remedy against dumping will prove adequate unless it operates immediately and automatically at port of entry.

Chairman Fordney for the committee stated that it is the intention to make the anti-dumping bill a part of the tariff act if the Senate does not pass it before the

tariff bill comes before the House. In that connection Mr. Fordney stated that it is the intention to report the tariff bill to the House not later than April 10.

ALUMINUM SULPHATE AND BAUXITE SITUATION

In the course of his testimony on behalf of the makers of heavy chemicals, S. W. Wilder of the Merrimac Chemical Co., Boston, said:

We believe the 1913 duty is inadequate to protect our industry and we have special reasons why we may expect that importation from now on of sulphate of alumina and allied compounds will increase. It is a fact that in Europe the production of sulphuric acid has been greatly increased since the war, and sulphate of alumina is a very natural vehicle for disposing of sulphuric acid, and we feel that this country may become a dumping ground for that product.

Mr. Wilder opposed a duty on bauxite. Due to the quality of imported bauxite, he said it would be a serious matter to put a duty on it. Representative Rainey, a member of the committee, took occasion to interpose the following with regard to the Aluminum Company of America:

That company started out as a \$90,000 corporation a few years ago, and now it is a \$10,000,000 corporation, controlling the production of aluminum in Canada as well as in the United States, and probably also in the world.

SUGGESTIONS ON AMMONIA

Among the recommendations made by William H. Bower of the Henry Bower Manufacturing Co. of Philadelphia was the following:

We would also suggest that aqua ammonia be transferred from the non-enumerated paragraph to a paragraph covering ammonia and its products at a specific rate of 1½c. per lb.; liquid anhydrous ammonia, 5c. per lb. This would show a duty per pound of ammonia in ammoniacal gas liquor of 2c.; of aqua ammonia 5c., and a calculated ad valorem for liquid anhydrous of about 14 to 15 per cent. The ammonia industry is an important one in this country, and serves the refrigerating trade by which our foodstuffs are stored and preserved.

Frederick W. Russe of the Mallinckrodt Chemical Works, St. Louis, declared that low priced chemicals are emanating in great volume from Germany, England, France and Italy. "We do not know," he said, "whether it is due to the cost of production, unloading or dumping. At any rate, they have their catalogues and lists down in South America, and they are taking the business that we and other manufacturers have developed before the war and during the war due to these abnormal conditions that are now existing."

MEDICINALS PRESENT SPECIAL PROBLEMS

In giving reasons why medicinal chemicals should be especially regarded in a tariff bill, Donald McKesson of McKesson & Robbins, New York, said:

Medicinal chemicals, owing to their nature and the care with which they have to be produced, chemicals for internal administration or hypodermic administration, require extreme purity, and therefore they cannot be manufactured on a very large scale. You cannot use the ordinary automatic apparatus which can be used on a large-scale manufacture. The workmen have to be intelligent and skilled, they have to be very closely supervised by high-grade chemists, who are very hard to obtain. Our chemical training in this country is not as high as it is abroad, and we have to require our chemists when we employ them to study further to increase their knowledge before they are really as efficient as they should be.

In reply to a question as to what proportion of his costs is labor, Mr. McKesson said:

I would say the average would be about 40 per cent or more; we went up to 75 per cent on some products. Our manufacture being almost entirely of medicinal chemicals, the cost is higher than suggested by Mr. Rosengarten previously, who also manufactures the heavier chemicals, where the cost of labor is very much lower.

He also testified to the effect that professional men in Germany are in desperate straits and are working for very low salaries. In addition he said:

Another reason for protection, or, rather, another reason why there should be a great endeavor in foreign countries to export to the United States is that it is absolutely necessary for them to establish credits in the United States, even at a sacrifice, and they are going to try and get the goods in here at any price they can get them in.

Germany, since the war, has increased her syndicate system. They are consolidating all of their factories, and they have their pools from yellow-dog funds, and everything they had before they are working in the same way to an intensified extent. That is a situation that we cannot reach on account of the Sherman law.

An example of a question put to numerous witnesses is shown by the following colloquy between Representative Garner of the committee and August Kochs, of the Victory Chemical Works, Chicago:

MR. GARNER. You are willing to take the difference between the cost of production here and abroad and take your chances with the foreigner?

MR. KOCHS. Yes, sir; absolutely, as a matter of business, and I think every manufacturer should be willing to do that.

POSSIBILITY OF RETALIATION IN CASE OF CAMPHOR

An interesting exchange took place between Representative Rainey and Nathan M. Clark, vice-president of the Celluloid Company, and representing the Pyroxylin Manufacturers' Association. It follows:

MR. RAINEY. Did it ever occur to you that Japan might retaliate and put an embargo on this camphor?

MR. CLARK. That might be entirely possible, and we could not ask this committee to help us in that instance, as we can now, with a tariff.

MR. RAINEY. If you put on a tariff high enough to keep her manufactures of camphor out of this country, why cannot she put an embargo against your raw camphor?

MR. CLARK. Yes; but then we would die by her blow and not by a blow from our committees.

MR. RAINEY. Then if we passed a tariff which would keep her manufactures of camphor out this market and she retaliated by putting an embargo on your raw material, you would be out of business entirely?

MR. FREAR. We have heard about those bugaboos before.

MR. RAINEY. It is not a bugaboo; it may actually happen.

MR. CLARK. We believe that is a potentiality, but we feel we would rather meet it the other way first.

By allotting all the way from two to fifteen minutes to each witness, a large number of representatives of the chemical industry were given an opportunity to appear before the committee during the hearing. Each discussed the necessity for protecting the products of his own manufacture.

TARIFF INFORMATION SURVEYS

In connection with the hearing, the United States Tariff Commission has furnished a series of tariff information surveys covering the greater portion of the commodities contained in the tariff act of 1913. The fact that the Tariff Commission was able to assemble and have printed, on such short notice, such comprehensive information has brought forth much favorable comment.

Edgar Fahs Smith, New President of the A. C. S.

Like Robinson Crusoe, Dr. Edgar Fahs Smith, the new president of the American Chemical Society, was born at York, but there the analogy ends. Robinson Crusoe went off by himself. Dr. Smith couldn't do such a thing, because there is no spot on earth so isolated or so distant but that many alumni of Pennsy would surely follow after him and before he had his hut half-way built they would be surrounding him, unhooking their ribs and opening their hearts, seeking advice. He has always been a teacher of chemistry, and while his laboratory methods are in use wherever chemistry has entered industry his whole career and activities have been academic. Born in Pennsylvania, he studied at Pennsylvania State College, where he took his degree as bachelor of science at the age of eighteen. At twenty he had achieved his Ph.D. at Göttingen, and since then he has been decorated nineteen times or more by various universities here and abroad, so that he is a twenty-fold doctor.

AS TEACHER AND AUTHOR

He was instructor in chemistry at the University of Pennsylvania from 1876 to 1881, professor of chemistry at Muhlenberg College 1881-83, at Wittenberg College 1883-1888, and from then on at the University of Pennsylvania again. From 1889 to 1911 he was vice-provost of the same university, and its provost from 1911 until last year. Although administrative duties interfered seriously with research, his contributions to the knowledge of electrochemistry, of electrolytic methods for the separation of metals, and of electrolysis generally have made him a leading authority in respect to these subjects. He is the author of several monumental works on electrochemistry, has translated Richter's inorganic and organic reference books; he has made signal contributions to the chemistry of tungsten and its compounds and has contributed with his advanced students over one hundred original papers to chemical literature. Besides this and more he has written a number of volumes of supreme merit which are biographies of leading American chemists of days that are past. We have spoken before of them. They distinguish the subjects of whom he writes. It is a good thing to give thanks unto the Lord, says the Psalmist, and we venture to add that it is also a good thing to know how to do it. Dr. Smith has this gift of words for tribute, for appeal, and for exposition, but he does not misuse it.

HONORED BY MANY SOCIETIES

Aside from membership in many learned societies, he was president of the American Philosophical Society for four years, from 1902 to 1906, and was once before, in 1898, president of the American Chemical Society. In 1914 he received the Elliot Cresson Medal from the Franklin Institute.

RETAINS HOLD ON ALUMNI

As a teacher Dr. Smith has had, in addition to unusual familiarity with his subject, a remarkably keen and appreciative understanding of his objects—who were his students. He knew his young men, and they knew that he knew them. When a new provost was to be chosen he was practically the unanimous choice of the alumni. He straightway became famous among college presidents by keeping every alumnus of the university posted by fre-

EDGAR FAHS SMITH
President American Chemical Society

quent personal letters as to what the university was doing. He proved himself also a faithful and competent administrator.

AN ADEPT AT EXPOSITION

He has a whimsical sense of humor which he employs in exposition, and he is singularly able to make clear the truth in regard to science and its use in everyday life in a manner at once simple and direct. Thus, while his activities have always been academic, his interests are unbounded and his sense of industry is practical and sane. There is no dilletantism in the questions he asks when he visits a chemical factory. His mind is somewhat of the Franklin type, being at once alive with curiosity, constructive in its working and habit, philosophical in its ordering, and yet always open, and usually with a little leaning toward the homely things of everyday life.

These expressions in regard to Dr. Smith have been gathered after diligent inquiry among the alumni of the University of Pennsylvania and from one of the leading educators of America, who is head of another important institution of learning.

British Columbia Paper Possibilities Interest Capital

A number of influential eastern Canadian pulp manufacturers have been in Victoria conferring with the officials of the British Columbia Government with a view to obtaining certain concessions in connection with the erection of two or three large pulp mills in the province. Provided satisfactory arrangements can be made, it is proposed to build a mill at Prince George which, it is said, will cost in the neighborhood of \$6,000,000.

New Tanning Process for Australian Shrub

A shrub growing principally in the gold fields of Australia has been found to possess properties suitable for tanning purposes, according to the *World Salesman*. Leather tanned by the extracts from this shrub is adjudged equal to the best, being especially useful in lining hats. Some excellent samples of fast dyes have also been extracted from this shrub. An extensive area has been granted a new enterprise by the West Australian minister for mines, over which the company will strip the bush to feed a tanning and extracting works.

The Woodpile and Its Relation to the Paper Industry

The Connecticut Valley branch of the Cost Association of the Paper Industry held its regular monthly meeting on Jan. 10 at the Hotel Nonotuck, Holyoke, Mass. Dr. Hugh P. Baker, secretary and treasurer of the American Pulp and Paper Association, was the principal speaker, and had for his subject "The Woodpile and Its Relation to the Paper Industry."

Dr. Baker reviewed the history of the forests in this country, particularly in New England, and pointed out that at first the forests were believed to be inexhaustible and that at times timber was cut down and burned up that the settlers might get at the land. To illustrate what the price of woodland was not long ago, the speaker told of exchanging in his early boyhood forty acres of timber for a bicycle, and said that he got the better of the bargain, taking into consideration that plenty of good woodland could be had at that time for 50c. an acre. It is only within the last two or three decades that forestry has been put on a scientific basis.

It has been claimed that the paper manufacturers have been using up the forests, but statistics show that only 8 per cent of the forests are being used for paper pulp purposes. Ten years ago the person who spoke of the need of reforestation would have been regarded as a theorist, but today the paper manufacturers realize that their industry is dependent upon forestry, as only 2 per cent of the paper made in the U. S. is of all rag stock.

A number of pulp manufacturers in the East have been forced to go into Canada for timber lands, and paper manufacturers are now importing wood pulp from Finland and Scandinavia. This would not have been necessary had we had a proper reforestation policy. The state of New York spent \$140,000,000 for lumber last year and 85 per cent of it came from the South and other states. Only 32 per cent of the land of New England is being farmed. There is enough idle land east of the Ohio River alone which, if properly reforested, would not only provide in time all the lumber that we need, but provide an export supply.

Reforestation in the case of hardwood is not so urgent, as there are large stands of these at present, but the shortage of rapid-growing evergreens for pulp-wood purposes is becoming acute. Reforested lands are about four times as prolific as virgin land and a cutting for pulp purposes could be made in about sixty to seventy-two years. To illustrate that reforestation could be made a profitable business venture, Dr. Baker said that in Germany before the war tenant farmers were being made to vacate the lands, as the owners could make more on their investments by planting forests.

He spoke of the Snell forestry bill now before Congress and said that bill, he hoped, would be passed at the next session and would form the charter of reforestation for this country and mark the first definite

step of the United States for forestation. "Not an industry can get along without our forests," he said, "and I hope to see these New England states great forest states through reforestation of tracts now idle."

Industrial Relations Conference

A large number of manufacturers, industrial relations managers and business executives attended a conference of the Industrial Relations Association of America on Jan. 7 at the Hotel Kimball, Springfield, Mass., at which was advocated a more intimate relationship between employer and employee in all connections, for the sake of more harmonious relations and consequent greater production. The meeting was held as a district convention of the association in co-operation with the Employment Managers Association and the Chamber of Commerce of Springfield.

Colonel B. A. Franklin, vice-president of the Strathmore Paper Co., West Springfield, Mass., was one of the principal speakers at the morning session. In order to obtain lower labor costs, he advised maintaining the best working conditions possible, and stated that adequate lighting of plant, maintenance of health and correct mental attitude of all employees were important factors making for the most pleasant places to work.

An informal discussion followed the afternoon session, at which presidents of the associations in different cities spoke. C. V. Derrick, employment manager of the American Bosch Magneto Corporation, Springfield, Mass., expressed a wish that the higher managers of the factory attend conferences of foremen and of other employees. F. M. Marsh of Boston noted the development of leaders among the employees as a growing function of the industrial relations manager. Mr. Ching of the United States Rubber Co. and Mrs. Jane Williams spoke on "What Readjustments Are Needed in Personnel, Service and Employment Work Under Present Conditions." C. J. Yeomans of New York spoke on "What Does Personnel, Service and Employment Work Mean to the Management?" Howard Cheney of the Cheney Silk Mills, South Manchester, Conn., discussed "New Problems in Industry and How to Meet Them."

Among the practices advocated by the several speakers as sound business were: Make the employee feel you are telling him the truth in all matters; work on the golden rule; a square-deal basis for all concerned; courtesy in meeting all men who apply for work, whether there is work or not; make it possible for foremen to handle labor problems within their own walls.

Nichols Medal Awarded to Dr. G. N. Lewis

The conferring of the Nichols Medal upon Dr. Gilbert N. Lewis of the University of California, by the New York Section of the A. C. S., which was to take place at the Chemists' Club, New York City, March 11, has been postponed until May 6, 1921.

This medal is awarded for some particularly important article which appears during the year in the *Journal* of the American Chemical Society and is to be bestowed upon Dr. Lewis for his paper entitled "The Third Law of Thermodynamics."

Chemicals Sold as Surplus Property

Chemicals, acids and explosives to the value of \$3,703,586.66 were sold prior to Jan. 1 by the director of sales of the War Department. This does not include chemicals, acids and explosives transferred or sold to Government departments or agencies.

Production of Camphor in the United States

Two of the largest consumers of camphor in the United States, E. I. du Pont de Nemours & Co. and the American Celluloid Co., have essayed to defeat, at least in part, the monopoly which the Japanese Government maintains on the supply of camphor by growing their own. This fact was brought out Monday evening, Jan. 10, by William R. Webb, assistant superintendent of the chemical plant of the Eastman Kodak Co., in his talk on "Camphor, Natural and Synthetic" before the Rochester Section of the American Chemical Society.

In 1910 the American Celluloid Co. set out a camphor-tree grove of 3,000 acres in Florida, and five years later the du Pont company began a much larger camphor-tree farm in the same state. The trees are pruned each year and the clippings distilled. From them nearly 2 per cent of their weight in camphor is obtained. When the trees stop growing rapidly they are cut down and the whole tree is distilled for camphor. In the meantime younger trees are kept ready to take the places of the older ones.

The Japanese Government controls the harvesting, reforesting and distilling of its camphor trees. At one time it produced practically all of the camphor used in the world, which is variously estimated at 10,000,000 lb. a year. To overcome this monopoly Germany and France began competing with the natural product through artificial camphor produced in their chemical plants from turpentine. The war stopped the production of this synthetic camphor, so that today the groves in Florida are the most formidable competitor of the Japanese monopoly.

January Meeting of the Indiana Section, A.C.S.

At the January meeting of the Indiana Section of the American Chemical Society at Indianapolis on Friday evening, Jan. 14, Dr. F. O. Andereg of Purdue University gave a talk on "Activated Nitrogen, Hydrogen and Oxygen." It was pointed out that these elements are in very stable molecular form, oxygen being the least inert of the three. Nitrogen is extremely inactive and hydrogen is between the others in activity. If some way can be found to activate these gases, then many reactions which do not occur under ordinary conditions can be brought out. The simplest way to activate most substances is to raise the temperature. Another very important method of activation is to use a catalyst. That subject is so great, however, that it was not discussed further, but the time was devoted to the description of several other methods.

In many chemical reactions where these elements are set free a certain proportion of the atoms or molecules come off in an activated condition. Thus "nascent" or active hydrogen is given off during the rapid solution of metals by acids, and the amount of activated gas is increased by speeding up the reaction. Sometimes electrolytic hydrogen is also very active. Similarly ozone, the commonest form of activated oxygen, is produced under favorable circumstances when acids act on peroxides, during electrolysis and during the slow oxidation of phosphorus or arsenic by moist air. There is always produced in nitrogen from the decomposition of ammonium nitrite some activated form which in contact with an alkali yields nitrates. The suggestion is made that this is initially the result of activated nitrogen.

Another method of activating substances is by ionic bombardment in the electric discharge. This, of course, is the common method of ozone manufacture and can be extended to other gases as well. Nitrogen synthesis by both the arc and silent discharge processes should be included here, and also the so-called synthesis of gasoline as covered by the Cherry patents. A very interesting activated nitrogen is that extensively studied by R. J. Strutt in England. This was produced by a condensed discharge at reduced pressure in pure nitrogen and has many interesting chemical effects. Certain Germans thought that the effects observed were due to the presence of oxygen and the discussion waxed hot and heavy until they all got together in London just before the war broke out and Strutt's claim of the production of the active form from pure nitrogen was vindicated. It was also found that a trace of many foreign gases greatly

accelerated the activation. Recently at the University of Chicago Dr. Wendt and Dr. Grubb have produced and studied a still more active form of nitrogen in the silent discharge. It is hoped that the study of activated gases will aid in the understanding of the structure of atoms, which is today a most fundamental problem.

Dr. I. H. Derby, director of the chemical division of the Republic Creosoting Co., spoke very ably supporting "a movement to establish the co-operative relation between science and the industries in Indiana." Dr. Mahin of Purdue University acknowledged the benefits to both the state industries and the universities of such a proposal and described the present status of the question at Purdue.

T.A.P.P.I. Prepares for Annual Meeting

The executive committee of the Technical Association of the Pulp and Paper Industry met in New York last week and completed preliminary arrangements for the annual meeting and banquet of the association, to be held in conjunction with the annual meeting of the American Pulp and Paper Association at the Waldorf-Astoria and the Hotel Astor, New York, during the week of April 11 to 15, 1921.

The convention will open with informal meetings of the executive committee and the chairmen of standing committees on Monday, April 11. The first general session of the association will convene in one of the meeting rooms of the Waldorf-Astoria at 10 a.m., Tuesday, April 12. The second general session in the afternoon will be devoted to the reading and discussion of scientific papers.

On the evening of Tuesday, April 12, at the Hotel Astor, the annual banquet will be given, at which Judge Charles F. Moore will be toastmaster.

The third general session of the annual convention of T.A.P.P.I. on Wednesday will feature symposiums on pulverized fuel and steam economy, conducted by Howard S. Taylor, chairman of the committee on light, heat and power; and new methods of grinding wood, conducted by the committee on groundwood, of which W. E. Munro is chairman.

Other symposiums, discussions and special papers for Wednesday and Thursday afternoons will be announced later.

Changes Considered in Methods of Industrial Alcohol Distribution

Whether or not changes in the present procedure in distributing industrial alcohol are advisable is being considered by a committee representing industrial alcohol producers. The appointment of the committee was the outgrowth of a meeting Jan. 19 with Prohibition Commissioner John F. Kramer. Mr. Kramer is anxious to know if illegal uses of this alcohol can be safeguarded further. The committee having the matter under consideration is made up as follows: Chairman, Henry J. Kaltenbach, New York, vice-president T. Fleischmann Co.; F. M. Harrison, United States Industrial Alcohol Co.; G. M. MacDowell, National Cereal Beverage Association; Charles Bacharach, Jefferson Distilling & Denaturing Co.; Albert H. Selling, David Berg Industrial Alcohol Co.; V. M. O'Shaughnessy, Rossville Distilling Co.; H. M. Gaylord, Kentucky Distilleries & Warehouse Co.; G. F. Dieterle, Federal Products Co.

Discussion of Western Metallurgical Problems

Dorsey A. Lyon, supervisor of stations, and other Bureau of Mines general officers, the superintendents of the Western experiment stations, Messrs. Van Barneveld, Duschak, Lind, Ralston and Varley, and the deans of co-operating mining colleges, Messrs. Butler, Probert, Lincoln, Merrill and Roberts, met in Berkeley, Cal., during the week of Jan. 24 for discussion of the work in hand and that contemplated by the bureau. Careful consideration was given to all phases of co-operative work of the bureau, colleges and industry, particularly any action designed to stimulate investigational work and the maintenance of close contact. "Flotation" was discussed by Dr. S. C. Lind, "A New Source of Alumina" by O. C. Ralston, and "Production of Sponge Iron" by the round table.

Status of the Nitrogen Corporation Bill in the House

Passage by the Senate of the nitrogen corporation bill removes none of the obstacles which face the bill in the lower house. On receiving the bill from the Senate, the House referred it to the Committee on Military Affairs, which has been considering the House bill on that subject. Representative Kahn, chairman of the committee, states that the bill will not be reported to the House until hearings have been held. Since the Military Affairs Committee has other matters before it which must be disposed of first, no effort has been made to fix a date for these hearings. Some are of the opinion that the bill will die in committee, but apparently the advocates of the bill are in the majority. The ranking Democrat is Representative Dent, of Alabama. Representative Anthony, of Kansas, ranks next to the chairman, and several other influential members are from agricultural sections which are advocating the passage of this legislation. A very influential member of the committee is Representative Fisher, of Tennessee. While there is much doubt as to the outcome of the struggle certain to take place in committee, it is apparent that the pigeonholing of the bill is by no means a foregone conclusion.

It is believed very generally that the bill can be passed in the House if it is brought to a vote. With the exception of Representative Mann, of Illinois, the Republican leaders in the House are understood to be opposed to the measure. With the end of the session approaching, however, the friends of the bill are in a position to exert great pressure on these leaders. If the bill is taken up in the House, it is believed it will be amended in several important particulars. One amendment doubtless will be the relief of the corporation from that provision of the Senate bill which requires it to make a profit from its inception. Another amendment doubtless will be to override the Senate in the matter of precluding Army officers from serving on the board. Undoubtedly the proponents of the legislation would predominate among the conferees, with the probability that the Senate conferees would recede on the more important of the House amendments. By the time the conference report is submitted, it is certain to be late in the present session, thereby offering a splendid opportunity for conducting a successful filibuster against the adoption of the conference report.

The bill, as passed by the Senate, has been put under the microscope during the past week by both its friends and its enemies. Due to the extensive way in which the bill was amended, it now is somewhat disjointed and contains a number of minor errors and conflicts, which, however, can be straightened out in the House and in conference. It is admitted that the provision of the bill making it necessary to pay 5 per cent interest on a sum equivalent to one-half of the original cost of the property cannot be complied with, especially during the first year of the corporation's existence. It was pointed out that it would be unfair to make the corporation pay interest on that considerable portion of the plant which would not be used by it.

It will be recalled that the Ordnance Department has been interested only in having the plant operated. Every effort was made to lease it to private interests. Arthur Glasgow spent six months of intensive effort to obtain a lessee, and at one time it appeared as though the United States Steel Corporation would lease the plant. Then came the suggestion that the Government operate the plant and with it was coupled later the agitation for the sale of the product as fertilizer. Whether or not the nitrogen corporation bill becomes a law, the Ordnance Department expects to redesign and reconstruct one of the units of No. 1 plant for experiments with the Haber process. Ordnance officials do not accept the frequently repeated statement made on the floor of the Senate that the cyanamide process has become obsolete. They point out that the cyanamide process continues in active use at thirty plants in eight countries, while the Haber process is in use nowhere outside of Germany. It is regarded as significant that the favorably located cyanamide plants in Germany are continuing to operate.

The amendment providing that no Army officers shall serve

on the board of the nitrogen corporation is criticized on the ground that each side in the controversy has recognized that the only excuse for the corporation is the fact that it would be in the interest of national defense. Even those who are most interested in obtaining fertilizer at the lowest possible cost admit that the principal purpose of the plant is to enable the country to secure nitrogen for war uses. Under those conditions to bar Army officers from the board is held to be on a par with another amendment to the bill which cut out the research laboratory provision. The laboratory would be essential to the full utilization of the plant for the advancement of knowledge as to the military aspects of nitrogen fixation.

There seems to be no objection in War Department circles to the provision of the bill which limits to 150,000 tons the amount of the nitrate reserve which may be sold. In this connection, it must be noted that it is 150,000 long tons, while current prices usually are quoted in short tons. With sterling exchange rising, and with other indications that Chilean nitrate will advance in price, some figure that \$9,000,000 is the probable realization which could be obtained from this 150,000 long tons of Chilean nitrate. Since the corporation would not need all of its money at once, the sale of the reserve could be spread out over a considerable period, so as not to demoralize or seriously affect the market. There has been considerable controversy over the Army's estimates made in connection with the nitrogen corporation project. The officers who made them call attention to the fact that sight is being lost of the prices and factors which prevailed at the time they were made.

Personal

Dr. MILO C. BURT, formerly of the ribbon factory of the Remington Typewriter Co. and of the Aetna Explosives Corporation, and WALTER R. HIBBARD, formerly of the U. M. C. Works of the Remington Arms Co., Inc., have opened a consulting and research laboratory in the McMahon-Wren Building, Bridgeport, Conn., under the name of Burt & Hibbard, Inc.

Dr. CARL J. ENGELDER, formerly chief chemist for the Pennsylvania Gasoline Co., is now assistant professor of analytical chemistry at the University of Pittsburgh, Pittsburgh, Pa.

Dr. COLIN G. FINK of the Chile Exploration Co., New York, will speak before the Pittsburgh Section of the American Electrochemical Society on "Modern Developments in Metallurgical Research," on Friday, Jan. 28. The meeting is to be held at the Mellon Institute, and will be preceded by a dinner at the University Club of Pittsburgh.

A. F. GREAVES-WALKER, production manager of the American Refractories Co., Pittsburgh, Pa., has been appointed chairman of the Refractories Division of the American Ceramic Society to take the place vacated by the resignation of A. V. Bleining.

Dr. OTTO KRESS, chairman of the committee on dyestuffs, Technical Association of the Pulp and Paper Industry, who has been in charge of the section of pulp and paper at the Forest Products Laboratory, Madison, Wis., for several years past, will resign from the service soon to accept a responsible position with the Consolidated Water Power & Paper Co., Wisconsin Rapids, Wis.

Dr. S. A. MAHOOD, who was in charge of research on wood cellulose and essential oils at the U. S. Forest Products Laboratory, Madison, Wis., has resigned to become associate professor in charge of organic chemistry at Tulane University, New Orleans, La.

Dr. E. E. MARBAKER, formerly chief engineer of Alexander Bros., Philadelphia, has accepted the position of chemist to the Cleveland Wire Division of the National Lamp Works of the General Electric Co.

HOMER F. STALEY, of the ceramic department of the Bureau of Standards at Washington, has resigned to be-

come affiliated with the Metal & Thermit Corporation, 120 Broadway, New York City, as ceramic engineer.

Dr. S. A. VONSOCHOCKY, general technical director of the Radium Luminous Material Corporation and the Radio Chemical Corporation, both of New York, has been elected president of the former company.

F. R. WADLEIGH, who has been export sales manager for Weston, Dodson & Co., Inc., has entered private practice as a consulting engineer. He is prepared to act in an advisory capacity on matters pertaining to the production, market and use of coal.

Dr. E. W. WASHBURN, director of ceramics at the University of Illinois, Urbana, Ill., has been appointed editor of the *Journal of the American Ceramic Society* beginning with the current year.

Obituary

EDWARD T. MCHUGH, for many years president of the McHugh Foundry Co. of Holyoke, died on Jan. 9, at the age of seventy-nine. Mr. McHugh's first important work was undertaken for the Government during the Civil War when he was stationed at Chattanooga, Tenn., in charge of reconstruction of railroads destroyed by the Confederates.

FERDINAND SCHLESINGER, head of the Newport Chemical Co., Milwaukee, Wis., died suddenly at Albuquerque, N. M., at the age of seventy. He was on his way to Pasadena, Cal., accompanied by his wife and son. Mr. Schlesinger was chairman of the board of directors of the Milwaukee Coke & Gas Co. and the Steel Tube Co. of America.

Current Market Reports

The Chemical and Allied Industrial Markets

New York, Jan. 24, 1921.

Actual trading in heavy chemicals during the past week has been very slow. However, there continued to be signs of a renewal of live interest. Improvement was noted in the extent of inquiries for miscellaneous chemicals. The slow but steady absorption of resale stocks has placed the market in a distinctly stronger position. The continued increasing strength of the alkalis is one of the most hopeful signs, and leading interests in the trade believe that this strength will soon spread throughout the general list of heavies.

The unceasing request from domestic consumers has forced manufacturers of *caustic soda* and *soda ash* to reduce prices on contracts. It is stated that the revision is not warranted by any lessened cost of production, but leading makers are willing to step in line with the general trend of affairs in an effort to stimulate business for forward shipments. The open quotation for *solid caustic soda* is now \$3.60 per 100 lb., basis 60 per cent, f.o.b. works, while 3½c. per lb. is the inside figure for round lots over the balance of the year. This cut represents a minimum of 15c. and a maximum decline of 25c. per 100 lb. *Light soda ash* is offered on contract at \$1.72½ per 100 lb. in single bags, basis 48 per cent, f.o.b. works, against a former figure of \$1.82½. Both chemicals on the spot market displayed a stronger tendency. Resale *caustic soda* is still obtainable below producers' prices, owing to the accumulated stocks in the hands of dealers, while the scarcity of *light ash* in second hands has forced the market to about the same level as that named by producers.

The demand for additional quantities of *white arsenic* has not been very active of late. Moderate offerings are obtainable at prices ranging from 11c. to 11½c. per lb. for domes-

tic material, while as low as 10½c. could probably be had on limited offerings of foreign. Resale lots of *formaldehyde* are in the market at prices ranging from 18c. to 19c. per lb., although most dealers are not eager to quote under 18½c. Producers quoted contracts at 20c. Manufacturers named 6½c. per lb. as the inside figure for standard *copper sulphate*, 99 per cent, in car lots. Outside makes occasionally reached the market at a trifle under this price, but there does not appear to be a great deal of material around. The inquiry is rather quiet at present and somewhat below that of recent years at this time.

Prominent sellers of *copperas* reported sales of prime goods on a basis of \$25 per ton f.o.b. works. It is doubtful whether any round lots could be purchased on the spot market under 1¼@2c. per lb. Sales of *yellow prussiate of soda* were reported at 17½c. per lb. and a few odd lots down to 17c. The tone of the market is firmer, however, and resale offerings are not as free as noted at the beginning of the month. Producers are asking 18c. for contracts, but admit that the inquiry for future shipments is rather quiet at the present time. Resale offerings of *caustic potash*, 88-92 per cent, are in the market at prices ranging from 14c. to 16c. per lb. Producers are quoting considerably above this figure, but admit that the demand is very light and confined solely to contract deliveries. There are sellers of foreign material for prompt shipment from Germany on a basis of 10c. per lb.

Sales of imported *tartaric acid* were reported at 33c. per lb., spot, duty paid, for the crystal variety. The powdered is quoted higher and sellers are asking 35@37c. per lb. Demand has not shown much activity of late and the feeling is still irregular regarding the future course of prices. Fused 60-62 per cent *sodium sulphide* is quoted by dealers at 5½@5¾c. per lb. for resale goods. The broken grade is considerably higher, and it is doubtful if much material could be obtained under 7c. per lb. The single strength crystals are now offered freely and the market remained more or less unchanged at 3½c. Sales of *sal ammoniac*, white, granular, 99 per cent, were reported down to 8½c. per lb. on spot. At the close of the week there were sellers at 8¼@9c. per lb. The demand has not been of any considerable volume so far and sellers were able to get business only by granting considerable price concessions.

COAL-TAR MARKET

Considering the increase in both inquiries and orders from different quarters of the market during the past week, many are led to believe that a period of improvement is ahead, and broader trading can be expected. Producers of various materials are holding to their views on prices and practically no reductions are announced. Most factors expect to see prices forced higher by the increasing activity among textile mills. While business in the woolen trade has not as yet shown much activity, it is expected that a better buying movement will be noted upon the naming of new prices by the American Woolen Co.

Trading in *dimethylaniline* was confined to a light volume. Producers are firm in their views on prices at 65@75c. per lb. Second hand lots are not being offered in any liberal quantities. The market in *dinitrotoluene* still holds to routine trading in small lots. There has been very little change in price on this item for some time. Quotations range from 27c. to 30c. per lb., depending on seller. Supplies of *H acid* are reported available in more quarters than recently noted and figures vary depending on sellers. In one direction \$1.30 was asked for a limited quantity, while leading producers named \$1.60. The demand for spot goods remained quiet and there was little talk on futures.

While the volume of trading in the market on *aniline oil* is still confined to small lots, the general tendency is toward a higher level of prices and where heretofore 23c. was readily done, the price is said to be harder to locate and 26@28c. per lb. was more generally quoted. The lack of any demand for *diphenylamine* seems to persist and with a fair volume of goods available, the market looked weak with quotations at 65@70c. per lb. The *anthracene* market attracted a little more attention during the past week in both offerings and inquiries. Domestic producers are not

thought to be in any better position on supplies and prices on the 80 per cent are quoted at 85c.@\$1 per lb.

There is very little change noted on *beta naphthol* of late and offerings are again noted at prices that show shading on producers' quotations and range from 35@40c. per lb. Prices on *paranitraniline* were named by producers from \$1 to \$1.05 per lb. for prompt delivery, with \$1.10 named on contract. Spot lots are around the market from second hands at figures well below manufacturers. The general quotation ranged from 90c. to 95c. per lb.

No change in *benzene* has been noted in the market. Prices in producers' hands remain around 30@35c. per gal. in drums and 28@32c. per gal. for the 90 per cent grade. Buying has been very limited on account of the slowness in consuming industries. *Naphthalene* producers are holding 9c. per lb. as the standard contract price over the year. There are lots to be had from dealers as low as 8c. per lb. for prime white goods, but it is understood that lots at these figures are being held more firmly and that in many cases holders have advanced their ideas to 8½@8¾c. per lb. No further imports have been noted, but stocks of foreign and domestic are still heavy in many quarters. The former price of 9c. per lb. on *phenol* is becoming increasingly hard to do, as stocks on spot are being cleaned up. Offers generally are made around 9½@10c. per lb., with more at the higher than at the lower figure.

The Chicago Market

Chicago, Jan. 21, 1921.

Heavy chemical prices in general have remained firm, the most notable exception being *blue vitriol*, which has been weakened by the low price prevailing in the copper market. Spot sales are recorded at 6¼c. per lb. for large crystals, and ½c. less for the small. Demand for small quantities is constant. All of the soda products have remained firm in price, all indications pointing to the practical elimination of second hand stocks. *Soda ash* on immediate delivery is quoted at \$2.20 per 100 lb. Contracts are reported at \$1.82½ per 100 lb. for 48 per cent f.o.b. works. *Caustic soda* has changed hands on the spot at as high as 4½c. per lb., but 4¼c. is probably more near the average market. Contracts are offered at \$3.75 per 100 lb. f.o.b. producing point. *Sal soda* is in poor demand, with price unchanged at \$2@ \$2.25 per 100 lb. Current demand for *bleaching powder* seems well covered by contracts which range around 3½c. per lb. Spots are offered somewhat lower, but little interest is shown.

Formaldehyde is easier and is reported as offered at 22c. per lb. in cars f.o.b. factory. Resale stock is offered at considerably below the market. *Alcohol*, *ethyl* grade, remains unchanged at \$5.10 per gal. for 190 proof, but *methyl* grade and *denatured* are both sharply off. Light demand on *denatured* has forced the price down to 68@72c. per gal. *Methyl*, 97 per cent, is down to \$1.35 per gal. Production is being sharply cut as large stocks are said to be in the hands of both producers and second hands. *Glycerine* remains quiet, as offers remain firm at 20c. per lb. for c.p. grade. *Quicksilver* remains weak, \$45 per flask representing the top of the market.

Chlorate of potash is on an uncertain price basis, the domestic being quoted at 16½@17c. per lb. for the crystals, and ½c. less for the powdered. *Caustic potash* is quoted all the way from 15c. to 20c. per lb. for domestic goods, with but few sales being closed. Imported goods are offered at much lower prices. *Carbonate of potash*, calcined, is offered at 14@17c. per lb., with little business resulting. *Chlorine*, liquid gas, is being bought in limited quantities only, and is quoted unchanged at 9@10c. per lb. *Salt cake* is in limited supply and price for immediate delivery ranges around \$53 per ton. *Sulphuric acid*, 60 deg., is quoted at \$15 per ton, but demand on this, as on other heavy acids, is light on the market.

VEGETABLE OILS

There is little doing in oils, as consuming factors have reduced operations to a minimum, operation being quoted as running below 25 per cent in most lines. *Linseed oil*

remains at 94c. per gal. in 1 to 5 bbl. lots from jobbers' stock and is quoted at around 80c. in carlots in cooperage. Actual sales of *coconut oil* in quantity have been made at 10½c. per lb. and Coast quotation is 9¼c. for Manila, in sellers' tanks. Demand is better than has been noted for some time. *Corn oil*, offered at 6½@6¾c. per lb. f.o.b. works, attracts no attention, and the same is true of *cottonseed oil* at 5¼@6c. for crude f.o.b. Texas points. Partial resumption of the textile industry holds some promise of better business in *red oil*, but no current market is in evidence.

NAVAL STORES

Contrary to general expectation, the advent of the new year failed to bring any renewal of activity in naval stores. Rosin and turpentine are equally quiet, the utter lack of export trade causing stocks to accumulate all along the line. *Turpentine* is quoted by jobbers in less than 5-bbl. lots at 96c. per gal.

COAL-TAR PRODUCTS

Business is utterly quiet, but prices are held firm, apparently because there is no hope of inducing business even through the medium of price cutting. *Naphthalene* is almost a drug on the market, quantities of imported material being available at 7½@8c. per lb. for the flakes and 9@9½c. for balls. Domestic is not so plentiful, and commands 1@1½c. per lb. higher price. Second hand holdings are confined principally to imported goods. *Toluene* at 35@37c. per gal. is in demand in routine quantities only and *benzene* seems a little more desired at 36c. than was the case a few weeks ago. Practically the entire line of intermediates may be covered in one phrase—no business. Prices are being held firmly, but it is probable that real money would secure radical concessions. The one exception is *aniline oil*, which is meeting fair demand at 25c. per lb.

The St. Louis Market

St. Louis, Jan. 21, 1921.

While there has been no startling increase in activity in the St. Louis market during the past two weeks an optimistic feeling is still very much in evidence. Quotations in practically no instances are showing any signs of weakness, though there has not been a very great demand. Producers give two reasons for this condition, one being a lowered production of some items and a resultant decreased stock. The other reason is the confidence that when demand does begin it will be concerted and prove more than equal to the stocks on hand.

Shipments on contracts have improved recently but are still slightly under normal. Contract renewals at current prices continue to be frequent but spot business has not recovered from its coma.

Shipments of the 98 deg. *sulphuric acid* have bettered and the quotation is holding firmly at \$24 per ton f.o.b. works. There is a lively market for the 66 deg. *sulphuric acid*, more sales being recorded for this strength than for any of the others. Producers are quoting \$20@\$21 per ton and 1¼c. per lb. in carboys, both prices at plant in St. Louis. The demand for the 60 deg. *sulphuric acid* has become quiet again but prices are being held at \$16 per ton and 1¼c. per lb. in carboys. There have been a number of inquiries for *oleum*, but as far as a real demand is concerned the market is quiet. The current quotation is \$28.50 per ton.

Muriatic acid is in fairly good demand, with supplies on hand continuing low. Producers are asking 1¼@2c. per lb. in carboys and \$25 per ton in bulk lots.

Quietness is the prevailing note in the *sodium bisulphate* market, with a flash of activity interspersed occasionally. Shipments have been quiet also. The current price is \$7@\$8 per ton.

Nitric acid has been very quiet, with quotations unchanging. The accepted prices are \$7 per 100 lb. for the 36 deg. test and \$10 per 100 lb. for 42 deg. *Standard mixed acid* is quoted at 1¼c. per lb. of sulphuric content and 11¼c. per lb. of nitric acid content.

Zinc chloride is slow at \$4.15 per 100 lb. for the 50 per cent test. U. S. Government supplies of *phenol* are being offered by a St. Louis producer at 12¼c. per lb.

The Iron and Steel Market

Pittsburgh, Pa., Jan. 21, 1921.

Demand for steel has not increased, either in the open market or against contracts. Generally speaking there is a decrease, making comparison with the average of December.

While the double market in steel products ended with 1920 by the independents coming down to the Steel Corporation level in prices, the Steel Corporation and the independents are in totally different positions. The independents seem to have expected a redistribution or leveling up process to occur, whereby they and the Steel Corporation would be in much the same position. Instead, there is a wide divergence. The independents are operating at about one-fourth of capacity on an average, while the Steel Corporation is operating at about 92 per cent, and even as to a continuance of the present rates of operation the Steel Corporation has the better outlook.

There is more or less similarity in the predictions as to future of the iron and steel market—that there will be no very material improvement in demand before the second half or third quarter of the year.

PRICES

There are reports of price cutting on the part of independents, but the really important point in the market is that there is not enough business being offered to induce general price cutting if the willingness to cut prices were complete. The real test is not being furnished. A sale of blue annealed sheets at \$3 a ton under the regular market of 3.55c., base, is reported, but that was 1,000 tons to the Standard Oil Co., on a very attractive specification. Orders so attractive are not common even in an active market, hence it seems to be a case of the exception that tests the rule. If \$3 is the limit of concession in such cases, an ordinary order would hardly bring out any shading.

Again, it is reported that mills in the Chicago district are shading prices on certain commodities by various amounts up to \$4 a ton, but in this case again it is a matter of the "Pittsburgh basing," the nominal market at Chicago being the Pittsburgh price plus freight, which is \$7.60, so that the Chicago mill would still be getting several dollars a ton more than the Pittsburgh price, and in a weak market the Pittsburgh basing is not expected to stand.

Regular prices remain as follows: Bars, 2.35c.; shapes, 2.45c.; plates, 2.65c.; grooved steel skelp, 2.45c.; universal mill skelp, 3.55c.; sheared skelp, 2.65c.; standard steel pipe, 57½ per cent basing discount; plain wire, 3.25c.; wire nails, \$3.25; blue annealed sheets, 10-gage, 3.55c.; black sheets, 28 gage, 4.35c.; galvanized sheets, 28-gage, 5.70c.; tin plate, \$7 per base box, 100 lb.; hoops, 3.05c.; hot-rolled strip, 3.30c.; cold-rolled strip, 6.25c. Standard railroad spikes are 3.65c.; cold-finished steel bars 3.60c., chain 7.25c. base, structural rivets 4c. and boiler rivets 4.10c. Rivets have come down somewhat in the past week, the other prices having been in force for several weeks.

PIG IRON

Bessemer and basic have been wholly inactive, and remain quotable at \$32 and \$30 respectively, valley furnaces, the levels to which they declined at the beginning of the year. Several sales of foundry iron in lots of about 500 tons each have established the quotable market at \$31.50 valley, a decline of \$1.50 in the week. Pig iron in the valley market has now declined nearly \$20 a ton since the high point of last August, and in proportion to the drop that has occurred the market has relatively little room for further decline. The greatly advanced freight rates represent several dollars per ton of pig iron by which pre-war prices could not be attained, and there are high wages in the Connellsville coke region, probably impossible of much reduction while the present high mining scale obtains in the union bituminous coal regions. The independents in the Lake Superior ore region are reducing wages by 15 per cent, but that does not indicate any close approach to pre-war prices for ore. The extreme estimate is that pig iron may get down to \$25 within the next six or nine months.

Nitric, 40 deg.....	lb.	.07 - .07	.08 - .08
Nitric, 42 deg.....	lb.	.08 - .09	.09 - .10
Oxalic, crystals.....	lb.	.18 - .18	.19 - .20
Phosphoric, Ortho, 50 per cent solution.....	lb.	.18 - .18	.18 - .19
Picric.....	lb.	.30 - .32	.35 - .40
Pyrogallol, resublimed.....	lb.	—	2.30 - 2.40
Sulphuric, 60 deg., tank cars.....	ton	—	14.00 - 15.00
Sulphuric, 60 deg., drums.....	ton	—	—
Sulphuric, 66 deg., tank cars.....	ton	18.00 - 19.00	—
Sulphuric, 66 deg., drums.....	ton	21.00 - 22.00	22.50 - 23.00
Sulphuric, 66 deg., carboys.....	ton	—	—
Sulphuric, fuming, 20 per cent (oleum) tank cars.....	ton	23.00 - 24.00	—
Sulphuric, fuming, 20 per cent (oleum) drums.....	ton	25.00 - 26.00	26.50 - 27.00
Sulphuric, fuming, 20 per cent (oleum) carboys.....	ton	32.00 - 35.00	40.00 - 42.50
Tannic, U. S. P.....	lb.	—	1.15 - 1.25
Tannic (tech.).....	lb.	.45 - .47	.48 - .50
Tartaric, crystals.....	lb.	—	.33 - .35
Tungstic, per lb. of WO.....	lb.	—	1.20 - 1.40
Alcohol, Ethyl.....	gal.	—	5.10 - 5.50
Alcohol, Methyl (see methanol).....	—	—	—
Alcohol, denatur ed, 188 proof.....	gal.	—	.66 - .70
Alcohol, denatur ed, 190 proof.....	gal.	—	.71 - .75
Alum, ammonia lump.....	lb.	.04 - .04	.05 - .05
Alum, potash lump.....	lb.	.05 - .06	.06 - .07
Alum, chrome lump.....	lb.	.13 - .13	.14 - .14
Aluminum sulphate, commercial.....	lb.	.02 - .02	.03 - .03
Aluminum sulphate, iron free.....	lb.	.03 - .03	.04 - .04
Aqua ammonia, 26 deg., drums (750 lb.).....	lb.	.06 - .07	.07 - .08
Ammonia, anhydrous, cyl. (100-150 lb.).....	lb.	.30 - .32	.33 - .35
Ammonium carbonate, powder.....	lb.	.12 - .12	.13 - .13
Ammonium chloride, granular (white salamoniac) (nominal).....	lb.	.08 - .09	.09 - .09
Ammonium chloride, granular (gray sal-ammoniac).....	lb.	.08 - .08	.09 - .09
Ammonium nitrate.....	lb.	.09 - .09	.10 - .10
Ammonium sulphate.....	lb.	.03 - .03	.04 - .04
Amylacetate.....	gal.	—	4.25 - 4.50
Amylacetate tech.....	gal.	—	3.50 - 3.75
Arsenic oxide, (white arsenic).....	lb.	.10 - .11	.11 - .11
Arsenic, sulphide, powdered (red arsenic).....	lb.	.15 - .15	.15 - .16
Barium chloride.....	ton	75.00 - 80.00	85.00 - 90.00
Barium dioxide (peroxide).....	lb.	.24 - .25	.26 - .27
Barium nitrate.....	lb.	.10 - .10	.10 - .11
Barium sulphate (precip.) (blanc fixe).....	lb.	.04 - .05	.05 - .06
Bleaching powder (see calc. hypochlorite).....	—	—	—
Blue vitriol (see copper sulphate).....	—	—	—
Borax (see sodium borate).....	—	—	—
Brimstone (see sulphur, roll).....	—	—	—
Bromine.....	lb.	.50 - .52	.54 - .56
Calcium acetate.....	100 lbs.	2.00 - 2.05	—
Calcium carbide.....	lb.	.04 - .04	.04 - .05
Calcium chloride, fused, lump.....	ton	27.00 - 29.00	30.00 - 32.00
Calcium chloride, granulated.....	lb.	.02 - .02	.02 - .03
Calcium hypochlorite (bleach'g powder).....	lb.	.02 - .02	.03 - .03
Calcium peroxide.....	lb.	—	1.25 - 1.30
Calcium phosphate, monobasic.....	lb.	—	.16 - .18
Calcium sulphate, pure.....	lb.	—	.05 - .06
Camphor.....	lb.	—	.85 - .90
Carbon bisulphide.....	lb.	.08 - .08	.09 - .09
Carbon tetrachloride, drums.....	lb.	.11 - .11	.11 - .12
Carbonyl chloride (phosgene).....	lb.	—	.60 - .75
Caustic potash (see potassium hydroxide).....	—	—	—
Caustic soda (see sodium hydroxide).....	—	—	—
Chlorine, gas, liquid-cylinders (100 lb.).....	lb.	.09 - .09	.10 - .10
Chloroform.....	lb.	—	.43 - .50
Cobalt oxide.....	lb.	—	3.70 - 3.80
Copper as (see iron sulphate).....	—	—	—
Copper carbonate, green precipitate.....	lb.	.22 - .22	.24 - .25
Copper cyanide.....	lb.	—	.40 - .50
Copper sulphate, crystals.....	lb.	.06 - .06	.06 - .07
Cream of tartar (see potassium bitartrate).....	—	—	—
Epsom salt (see magnesium sulphate).....	—	—	—
Ethyl Acetate Com. 85%.....	gal.	—	1.05 - 1.10
Ethyl Acetate pure (acetic ether 98% to 100%).....	—	—	—
Formaldehyde, 40 per cent.....	lb.	.18 - .18	.19 - .20
Fusel oil, ref.....	gal.	—	3.50 - 3.60
Fusel oil, crude.....	gal.	—	2.75 - 3.00
Glauber's salt (see sodium sulphate).....	—	—	—
Glycerine, C. P. drums extra.....	lb.	—	.20 - .21
Iodine, resublimed.....	lb.	—	3.85 - 4.00
Iron oxide, red.....	lb.	—	.10 - .20
Iron sulphate (copperas).....	100 lb.	1.75 - 2.00	2.25 - 2.50
Lead acetate, normal.....	lb.	—	.14 - .16
Lead arsenate (paste).....	lb.	.13 - .14	.14 - .15
Lead nitrate, crystals.....	lb.	—	.90 - 1.00
Litharge.....	lb.	.09 - .09	.09 - .10
Lithium carbonate.....	lb.	—	1.50 - 1.50
Magnesium carbonate, technical.....	lb.	.10 - .11	.11 - .12
Magnesium sulphate, U. S. P.....	100 lb.	2.50 - 3.00	—
Magnesium sulphate, commercial.....	100 lb.	—	1.50 - 1.75
Methanol, 95%.....	gal.	—	1.30 - 1.40
Methanol, pure.....	gal.	—	1.50 - 1.70
Nickel salt, double.....	lb.	—	.12 - .12
Nickel salt, single.....	lb.	—	.13 - .13
Phosgene (see carbonyl chloride).....	—	—	—
Phosphorus, red.....	lb.	.45 - .46	.47 - .50
Phosphorus, yellow.....	lb.	—	.35 - .37
Potassium bichromate.....	lb.	.15 - .16	.16 - .16

		Carlots	Less Carlots

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude.....	lb.	\$1.10 — \$1.15
Alpha-naphthol, refined.....	lb.	1.45 — 1.50
Alpha-naphthylamine.....	lb.	.40 — .44
Aniline oil, drums extra.....	lb.	.26 — .28
Aniline salts.....	lb.	.27 — .30
Anthracene, 80% in drums (100 lb.).....	lb.	.85 — 1.00
Benzaldehyde (f.f.c.).....	lb.	2.00 — 2.10
Benzidine, base.....	lb.	1.00 — 1.10
Benzidine sulphate.....	lb.	.85 — .90
Benzoic acid, U.S.P.....	lb.	.70 — .75
Benzoate of soda, U.S.P.....	lb.	.75 — .85
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.).....	gal.	.28 — .32
Benzyl chloride, 95-97%, refined.....	lb.	.30 — .35
Benzyl chloride, tech.....	lb.	.25 — .30
Beta-naphthol benzoate.....	lb.	3.50 — 4.00
Beta-naphthol, sublimed.....	lb.	.75 — .80
Beta-naphthol, tech (nominal).....	lb.	.35 — .40
Beta-naphthylamine, sublimed.....	lb.	2.25 — 2.40
Cresol, U. S. P., in drums (100 lb.).....	lb.	.16 — .18
Ortho-cresol, in drums (100 lb.).....	lb.	.23 — .25
Cresylic acid, 97-99%, straw color, in drums	gal.	.95 — 1.00
Cresylic acid, 95-97%, dark, in drums.....	gal.	.90 — .95
Cresylic acid, 50%, first quality, drums.....	gal.	.65 — .75
Dichlorobenzene.....	lb.	.06 — .09
Diethylaniline.....	lb.	1.25 — 1.30
Dimethylaniline.....	lb.	.65 — .75
Dinitrobenzene.....	lb.	.30 — .32
Dinitrochlorobenzene.....	lb.	.25 — .30
Dinitronaphthalene.....	lb.	.35 — .40
Dinitrophenol.....	lb.	.40 — .45
Dinitrotoluene.....	lb.	.27 — .30
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 — .40
Diphenylamine.....	lb.	.65 — .70
H-acid.....	lb.	1.40 — 1.55
Meta-phenylenediamine.....	lb.	1.25 — 1.30
Monochlorobenzene.....	lb.	.14 — .16
Monoethylaniline.....	lb.	1.75 — 2.25
Naphthalene crushed, in bbls. (250 lb.).....	lb.	.08 — .08½
Naphthalene, flake.....	lb.	.08 — .08½
Naphthalene, balls.....	lb.	.09 — .09½
Naphthionic acid, crude.....	lb.	.70 — .75
Nitrobenzene.....	lb.	.12 — .15
Nitro-naphthalene.....	lb.	.40 — .50
Nitro-toluene.....	lb.	.18 — .25
Ortho-amidophenol.....	lb.	3.20 — 3.75
Ortho-dichlor-benzene.....	lb.	.15 — .20
Ortho-nitro-phenol.....	lb.	.75 — .80
Ortho-nitro-toluene.....	lb.	.20 — .28
Ortho-toluidine.....	lb.	.25 — .30
Para-amidophenol, base.....	lb.	1.90 — 2.00
Para-amidophenol, HCl.....	lb.	2.20 — 2.25

Para-dichlorobenzene.....	lb.	.15 — .25
Paranitroaniline.....	lb.	.93 — 1.00
Para-nitrotoluene.....	lb.	1.05 — 1.15
Para-phenylenediamine.....	lb.	2.20 — 2.35
Para-toluidine.....	lb.	1.50 — 1.60
Phthalic anhydride.....	lb.	.55 — .60
Phenol, U. S. P., drums (dest.), (240 lb.).....	lb.	.10 — .12
Pyridine.....	gal.	2.00 — 3.50
Resorcinol, technical.....	lb.	2.25 — 2.50
Resorcinol, pure.....	lb.	3.60 — 3.80
Salicylic acid, tech., in bbls. (110 lb.).....	lb.	.25 — .28
Salicylic acid, U. S. P.....	lb.	.29 — .35
Salol.....	lb.	.85 — .95
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.28 — .32
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.16 — .18
Sulphanilic acid, crude.....	lb.	.30 — .35
Tolidine.....	lb.	1.45 — 1.60
Toluidine, mixed.....	lb.	.40 — .45
Toluene, in tank cars.....	gal.	.30 — .32
Toluene, in drums.....	gal.	.33 — .35
Xylidines, drums, 100 gal.....	lb.	.45 — .50
Xylene, pure, in drums.....	gal.	.42 — .45
Xylene, pure, in tank cars.....	gal.	.45 — .50
Xylene, commercial, in drums, 100 gal.....	gal.	.33 — .35
Xylene, commercial, in tank cars.....	gal.	.30 — .35

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark.....	lb.	\$0.24 — \$0.26
Beeswax, refined, light.....	lb.	.27 — .28
Beeswax, white pure.....	lb.	.35 — .40
Carnauba, No. 1.....	lb.	.85 — .90
Carnauba, No. 2, North Country.....	lb.	.35 — .40
Carnauba, No. 3, North Country.....	lb.	.19 — .20
Japan.....	lb.	.19 — .20
Montan, crude.....	lb.	.07 — .08
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.05 — .05½
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.04½ — .05
Paraffine waxes, refined, 118-120 m.p.	lb.	.06½ — .06¾
Paraffine waxes, refined, 125 m.p.	lb.	.07 — .07½
Paraffine waxes, refined, 128-130 m.p.	lb.	.07 — .08
Paraffine waxes, refined, 133-135 m.p.	lb.	.09½ — .09¾
Paraffine waxes, refined, 135-137 m.p.	lb.	.10½ — .11
Stearic acid, single pressed.....	lb.	.13 — .13½
Stearic acid, double pressed.....	lb.	.13½ — .14
Stearic acid, triple pressed.....	lb.	.14½ — .14¾

Flotation Oils

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr. 0.930-0.940.....	gal.	\$1.70
Pine oil, pure, dest. dist.....	gal.	1.60
Pine tar oil, ref., sp.gr. 1.025-1.035.....	gal.	.48
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990.....	gal.	.75
Pine tar, ref., thin, sp.gr. 1.080-1.960.....	gal.	.36
Turpentine, crude, sp. gr. 0.900-0.970.....	gal.	1.20
Hardwood oil, f.o.b. Mich., sp.gr. 0.960-0.990.....	gal.	.37
Pinewood creosote, ref.....	gal.	.55

Naval Stores

The following prices are f.o.b. New York for carload lots.

Rosin B-D, bbl.....	280 lb.	\$8.75 — .
Rosin E-I.....	280 lb.	8.75 — .
Rosin K-N.....	280 lb.	8.75 — .
Rosin W. G.-W. W.....	280 lb.	9.00 — .
Wood rosin, bbl.....	280 lb.	9.00 — .
Spirits of turpentine.....	gal.	.76 — .
Wood turpentine steam dist.....	gal.	.72 — .
Wood turpentine, dest. dist.....	gal.	.71 — .
Pine tar pitch, bbl.....	200 lb.	— 8.50
Tar, kiln burned, bbl. (500 lb.).....	bbl.	— 15.00
Retort tar, bbl.....	500 lb.	15.00 — 15.50
Rosin oil, first run.....	gal.	.52 — .
Rosin oil, second run.....	gal.	.54 — .
Rosin oil, third run.....	gal.	.62 — .

Solvents

73-76 deg., steel bbls. (85 lb.).....	gal.	\$0.41
70-72 deg., steel bbls. (85 lb.).....	gal.	.39
68-70 deg., steel bbls. (85 lb.).....	gal.	.38
V. M. and P. naphtha, steel bbls. (85 lb.).....	gal.	.30

Crude Rubber

Para-Upriver fine.....	lb.	\$0.18½ — \$0.19
Upriver coarse.....	lb.	.14 — .14½
Upriver caucho ball.....	lb.	.14½ — .14¾
Plantation—First latex crepe.....	lb.	.21 — .
Ribbed smoked sheets.....	lb.	.20 — .
Brown crepe, thin, clean.....	lb.	.18 — .
Amber crepe No. 1.....	lb.	.20 — .

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls.....	lb.	\$0.09½ — \$0.10
Castor oil, AA, in bbls.....	lb.	.11 — .11½
China wood oil, in bbls. (f.o.b. Pac. coast).....	lb.	.08½ — .09
Cocoonut oil, Ceylon grade, in bbls.....	lb.	.12½ — .13
Cocoonut oil, Cochín grade, in bbls.....	lb.	.12½ — .13
Corn oil, crude, in bbls.....	lb.	.08½ — .09½
Cottonseed oil, crude (f. o. b. mill).....	lb.	.06 — .07
Cottonseed oil, summer yellow.....	lb.	.09 — .09½
Cottonseed oil, winter yellow.....	lb.	.09½ — .09¾
Linseed oil, raw, car lots (domestic).....	gal.	.76 — .77
Linseed oil, raw, tank cars (domestic).....	gal.	.69 — .70
Linseed oil, boiled, car lots (domestic).....	gal.	.78 — .79

Olive oil, commercial.....	gal.	\$2 50	—	\$2 60
Palm, Lagos.....	lb.	.07 $\frac{1}{2}$	—	.08
Palm, Niger.....	lb.	.07	—	.07 $\frac{1}{2}$
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.07	—	.07 $\frac{1}{2}$
Peanut oil, refined, in bbls.....	lb.	.13	—	.13 $\frac{1}{2}$
Rapeseed oil, refined in bbls.....	gal.	1 10	—	1 15
Rapeseed oil, blown, in bbls.....	gal.	1 20	—	1 25
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.08 $\frac{1}{2}$	—	.09
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.05 $\frac{3}{4}$	—	.06

FISH

Light pressed menhaden.....	gal.	\$0 53	—	\$0 55
Yellow bleached menhaden.....	gal.	.55	—	.58
White bleached menhaden.....	gal.	.57	—	.60
Blown menhaden.....	gal.	1.00	—	—

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	22.00	—	26.00

Industrial

Financial, Construction and Manufacturers' News

Colorado

GARFIELD—Harrison Petroleum Co., Grand Valley, is having plans prepared for the construction of 1,000 ton shale oil refinery for manufacture of gasoline, lubricating oils and paraffine. Estimated cost \$500,000. H. C. Wolf, Oklahoma City, engr.

Idaho

KELLOGG—Bunker Hill & Sullivan M. & C. Co. plans to build electrolytic zinc refinery, with 25 ton metallic zinc capacity per day. Above project will be in conjunction with lead concentrator and smelter of company, here. Estimated cost \$1,000,000. F. M. Smith, dir.

Iowa

BELLE PLAINE—The Bd. of Educ. is having plans prepared for the construction of a 2 story, 83 x 130 ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$100,000. C. R. Ahrens, Secy. C. A. Dieman & Co., 408 Granby Bldg., Cedar Rapids, archt.

CORYDON—The Bd. of Educ. will receive bids until Feb. 10 for the construction of a 3 story, 67 x 121 ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$160,000. D. T. Sellenberger, Pres. W. Gordon, 319 Hubbell Bldg., Des Moines, Archt. noted Dec. 1.

Kansas

PARSONS—City is having plans prepared for rehabilitation of waterworks plant including installation of filter equipment and machinery for 6,000,000 gal. capacity. Estimated cost \$350,000,000. Burns & McDonnell Engr. Co., Interstate Bldg., Kansas City, Mo., assigning and consulting engs.

Maine

RICHMOND—THE City Waterworks plans to construct a filtration plant. Cost between \$18,000 and \$20,000.

Michigan

BENTON HARBOR—City is having plans prepared for installation of filtration plant. Estimated cost \$100,000. Greeley, Pearse & Hansen, 39 West Adams St., Chicago, engs.

CADILLAC—St. Mary's Hospital will receive bids in the early spring for construction of 3 story hospital. A chemical laboratory will be installed in same. Estimated cost \$250,000. E. Brielmaier Sons, 432 Bway., Milwaukee, archts.

FENTON—The Bd. of Educ., c/o M. B. Smith is having plans prepared for the construction of a 2 story high school. A chemical laboratory will be installed in same. Estimated cost, \$200,000. Van Leyen, Schilling, Keough & Reynolds, 3440 Cass Ave., Detroit, archt.

Minnesota

ALBERT LEA—The Central Fdry. Co., Marshalltown, Ia., plans to construct a 1 story, 100 x 200 ft. factory here. Estimated cost, \$50,000.

EVELETH—City has received bids for construction of a filtration plant, from Lawrence McCann Co., Eveleth, \$178,350; Roberts Mfg. Co., Eveleth, \$179,870; Phelps-Drake Co., 631 Metropolitan Life Bldg., Minneapolis, \$184,730. Noted Sept. 17.

Montana

MILES CITY—Custer Co. Free High School has awarded the contract for construction of 3 story, 152 x 210 ft. high school, to Lease & Liegland, Great Falls. Estimated cost \$195,000. A chemical laboratory will be installed in same. Noted Jan. 12.

Nebraska

NELSON—Bd. of Educ. has plans prepared for the construction of a 2 story high school. A chemical laboratory will be installed in same. Estimated cost, \$90,000. H. D. Pampel, 402 Finance Bldg., Kansas City, Mo., archt.

New York

BROOKLYN—W. Scandon Paper Box Co. will build a 2 story, 40 x 100 ft. factory at 150 Skillman St. Estimated cost, \$35,000.

CARTHAGE—The Northern Development Syndicate plans to construct a commercial size ore reduction plant and electric smelting furnace.

OLEAN—England, Walton & Co., Inc., plans to rebuild its six tannery buildings which were recently destroyed by fire. Estimated cost, \$200,000.

North Dakota

JAMESTOWN—The city plans to improve waterworks system, including reservoir and water softener. Estimated cost, \$60,000. H. H. Hurning, city engr.

Ohio

CLEVELAND—The Frank Dry Cleaning Co., 1361 East 55th St., has awarded the contract for the construction of a 2 story, 44 x 76 ft. factory on East 60th St. and Bonna Ave. Estimated cost, \$50,000. M. H. Merver, mgr.

WEST CARROLLTON—American Envelope Co. is having plans prepared for construction of 2 story, 60 x 110 ft. factory, on Main St. Estimated cost \$50,000. E. J. Mountstephen, 803 U. B. Bldg., Dayton, archts.

YOUNGSTOWN—The Bd. of Educ., 16 West Wood St., will soon award the contract for the construction of a 2 story, 250 x 250 ft. high school on Ohio St. A chemical laboratory will be installed in same. Estimated cost, \$1,000,000. C. F. Owsley, 1301 Mahoning Bank Bldg., archt.

Oregon

PORTLAND—Portland Vegetable Oil Mills Co. plans to build manufacturing plant, to have 100 ton vegetable oil capacity. Estimated cost \$450,000. C. A. Painton, pres.

Pennsylvania

SUGAR NOTCH—City plans to construct a 2 story, 100 x 120 ft. high school. A chemical laboratory will be installed in same.

South Dakota

MISSION—The Bd. of Educ., c/o S. D. Hickey, Co. Supt. of Schools, plans to construct a 2 story consolidated school. A chemical laboratory will be installed in same. Estimated \$125,000. Architect not announced.

SIOUX FALLS—The Bd. of Educ. is having plans prepared for the construction of a 3 or 4 story high school. A chemical laboratory will be installed in same. Estimated cost, \$400,000. Perkins & McWayne, 324 Paulton block, archts. H. S. Hillehoe, supt. of schools.

Texas

EASTLAND—The city has awarded the contract for the construction of storm and sanitary sewers and a sewage disposal plant to include a septic tank, sprinkling filter and sludge bed. Estimated cost, \$185,000. Noted Dec. 8.

FORT WORTH—The Masonic Grand Lodge of Texas, Waco, has awarded the contract for the construction of a 2 story hospital. A chemical laboratory will be installed in same. Estimated cost, \$90,000.

FT. WORTH—The Peden Iron & Steel Co., Main and Daggett Sts., is having plans prepared for the construction of a steel roller mill and fabricating plant. Estimated cost, \$1,000,000. D. R. Luce, Ft. Worth, engr.

RANGER—Chestnut & Smith are having plans prepared for the construction of a casinghead gasoline plant. Estimated cost, \$500,000.

RANGER—The Humble Oil & Refining Co., Goggan Bldg., Houston, is having plans prepared for the construction of a topping plant in connection with its oil refinery. Estimated cost, \$500,000.

Washington

MILLWOOD—The Inland Empire Paper Co. has awarded the contract for the construction of a brick and concrete addition to its paper mill. Estimated cost, \$85,000.

SEATTLE—The Rothert Process Steel Co., 622 Othello St., plans to construct several buildings and install one or two 15-

ton electric steel furnaces and other equipment, for manufacture of ingots, bar steel and high grade steel products from raw materials. E. H. Rothert, pres.

West Virginia

ROUND BOTTOM—H. J. Booth, 1675 Beechwood St., Pittsburgh, Pa., has purchased a site and plans to build a glass plant.

Wyoming

CASPER—E. LeRoy, Sistersville, West Virginia, plans to build plant, here, for manufacture of glass.

Ontario

LONDON—I. O. D. E., c/o Watt & Blackwell, archts., Bank of Toronto Chambers, has awarded the contract for the construction of a 4 story, 110 x 200 ft. children's hospital on Ottaway Ave. A chemical laboratory will be installed in same. Estimated cost, \$200,000.

WINDSOR—The Municipal School Bds. of Windsor and Walkerville plans to construct a 3 story technical school. A chemical laboratory will be installed in same. Estimated cost, \$500,000.

British Columbia

PRINCE RUPERT—Prince Rupert Pulp & Paper Co., Vancouver, plans to erect plant, here, for the manufacture of pulp and paper, to be in conjunction with general lumbering business. Estimated cost \$4,000,000.

Quebec

MONTANE—The Hammermill Paper Co., Erie, Pa., will receive bids the latter part of January for building a pulp and paper mill, here. Estimated cost, \$1,000,000.

MONTREAL—W. R. Cuthbert & Co., 41 Duhe St., plans to build a 3 story brass finishing factory. Estimated cost, with equipment, \$85,000.

ST. ANGELE DE LAVAL—The Brown Pulp & Paper Co. is having plans prepared for the construction of a pulp and paper mill. Estimated cost, \$1,500,000.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its annual meeting Feb. 21 to 24 at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting Feb. 14 to 17 in New York City.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

COMMON BRICK MANUFACTURERS' ASSOCIATION OF AMERICA will hold its annual meeting at the Hotel Pennsylvania, New York City, Jan. 31 to Feb. 4.

NATIONAL PETROLEUM CONGRESS will meet at the Hotel Baltimore, Kansas City, Mo., March 22 to 25.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

THE SEVENTH EXPOSITION OF CHEMICAL INDUSTRIES will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: Feb. 11, American Electrochemical Society, joint meeting with Society of Chemical Industry, American Chemical Society and Société de Chimie Industrielle; March 11, American Chemical Society; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society, Nichols Medal award; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Number 5

A Question That Will Not Down

SOME time ago we asked, "Who is a chemist?" and the question has not been answered yet. But many have been asking it repeatedly, and some earnest men are rather insistent in the query. The New Jersey Chemical Society, at its October meeting, appointed a committee consisting of F. D. CRANE, G. F. COTTLE and C. P. TITUS to ascertain and report whether or not it appears advisable to form an American Institute of Chemistry. These gentlemen propose that such an institute might:

1. List all persons who wished to be considered chemists in any sense of the word, all chemical products and all chemical industries; the lists to be made without charge and to be public. It would be a kind of "Chemical Who's Who," containing each man's record of himself.

2. Register chemists who furnish definite, accurate information as to education and experience, such information and all other pertinent facts to be subject to independent investigation and to be available to inquirers under reasonable regulations. In other words, the Institute would undertake to check up the records. For registration a moderate fee would be charged.

3. Certify chemists according to their proficiency in the various branches of chemical education and experience after the candidate has passed a definite examination suited to the type of certificate desired. A fee to be charged for such examination.

In addition to the foregoing it is also proposed to urge upon the national and state legislators such legislation as may prove to be desirable or needed, and to maintain communication with all institutions which train chemists, with a view to achieving some measure of harmony in the various courses.

It is very easy to pick to pieces any proposal for something new. At first glance it seems to us that items 1 and 2 should be consolidated, on the ground that a general listing of all claimants would contain a great deal of misinformation. It would also lack many of the best names as well as a great many facts of leading importance. A severe supervision would be better, we think, because otherwise the chemical quacks would get their names in, and then attempt to profit by it. The registration feature appeals to us as the better course. As for the certification feature, it is a great deal to ask of a man in practice to pass an examination, and we doubt if the best and most experienced men would be willing to undergo it.

But these questions are only preliminary. Of course the committee is not tied to any particular course; it is seeking wisdom and we desire to give it all the encouragement we can in the great quest of "Who is a chemist?"

Back of all this seeking, and hastening it a little, is a cloud no bigger than a man's hand perhaps, but a cloud nevertheless. In Chicago, and here in New York

and elsewhere, a number of men engaged in laboratories have formed labor unions and associated themselves with the American Federation of Labor. It is not a pleasant prospect. When a man enters upon a profession he takes upon himself professional obligations. He pays less for his education than it costs. The institution that was endowed to give him his education was not designed primarily to make him rich; it was designed to prepare him to render service. He is a man set apart for special work. When we think of the immense forces still hidden in the secrets of nature which may be available to the next generation, the responsibilities of men of the exact sciences are greater by far than the responsibilities of lawyers and practitioners of medicine.

It may be that men working all day as laboratory helpers or in making color carbons or other routine tests, week in and week out, are underpaid; but they are not working as chemists. Whatever their training and preparation may be, they are no more entitled to the honorable appellation than the prescription man in the drug store. They may be chemists, but they are not practicing chemistry. If they want to join a drug clerks' union or a steel testers' federation, it is their right and privilege, but to call them chemists is a mistake. A real chemist differs from a craftsman in that his mind is trained to meet a multiplicity of problems. He is entitled to the distinction of his calling.

On the other hand, the proposal to license chemists is fraught with difficulties. When this is done by state legislation it prevents the best man who may live somewhere else from rendering his much-needed service. If a national license system is organized it will grow too big to be efficient and if politics creeps in it will create an unbearable situation. Engineers are now licensed in several states and so far as we have learned the system only adds red tape and chokes progress.

Our advice to our New Jersey friends is to drop the idea of a new Institute and to go ahead in New Jersey; to try out some system of listing and registering in that state alone, and when they have the work pretty well along so that they have a census of, say, half the chemists and chemical industries and chemical products of the commonwealth, the state government may come in and complete the job. It may prove to be of great value. New Jersey is important in chemical industry. If information as to men, industries and materials were available it would give the state a distinct and peculiar lead. Other chemical industries would flock there to be near what they need and to be where they know that competent professional men foregather. Then if New Jersey works it out other states may follow. In the process of working it out we may discover who a chemist is.

Power Plant Wastes Contain Recoverable Chemicals

A PRELIMINARY survey of a certain large city steam-generating station indicates the possible recovery of 220 tons of sulphuric acid per day from the waste flue gases. Tests made at the same time reveal the possible recovery of 10,000 lb. of potash (K_2O) per month and the economical production of 19,100 tons of slag cement during the same period.

The estimates were based on the weight of slag and soot for a given number of steaming hours, the total number of steaming hours for one month, samples of flue dust and combustion chamber slag, total coal burned, total refuse for one month and analyses of slag and soot samples, together with sulphur determinations of weekly station ash samples.

It was proposed to recover the acid with Cottrell precipitators, the potash by leaching the various wastes with hot water which was available and to produce the cement by addition of a suitable proportion of limestone to the slag. The gross income from the three products was estimated at \$330,000 per month.

Public utilities enter the oil and mining business these days, and with considerable profit. It is not unlikely they will gain by attention to such chemical products as involve plant and sewage wastes and which come within the field of electrochemistry. A good chemical engineer would be an asset to any large power company.

Stifling Water-Power Development Through Inaction

WITH a keen perception of political values Congress is giving attention to certain phases of legislation of doubtful value. Over the veto of the President it has passed legislation providing for loans to farmers, and with a great show of interest in the public welfare it is considering emergency tariff legislation. At the same time a bill of tremendous import to industrial progress is allowed to rest peacefully in the hands of the select committee of the House of Representatives on water power. Political expediency evidently dictates this course, but the chemical industries, with others that need power for effective development, may well ask why class legislation is crowding out their legitimate needs.

We refer to the bill introduced by Representative ESCH (H.R. 15126) providing slightly enlarged authority for the Federal Power Commission to employ appropriate personnel, either from outside the Government or by transfer from other executive departments. At the present time there is pending before the Power Commission a mass of applications for power development which represents 13,000,000 horsepower in potential energy supply. This is five times as much business as has been handled in over twenty years by all of the executive departments previously in charge of these affairs. And to care for it Congress permits these departments to loan a few members of their staff to the Power Commission to do the work. At the present rate one hundred years will be required to care for the applications already pending, and more arrive every day.

Chemical industry, especially the metallurgical and electrochemical industries, need extensive power developments in all parts of the country so that one of their raw materials, electrical energy, will be available in adequate quantity at reasonable price. They do not ask that the Federal Government go out and spend money on this development. They can reasonably de-

mand, and they do, that the Federal Government permit this commission to do business effectively and promptly, so that the horsepower now going to waste can be put into productive use for the benefit of all. The electrical industry, the prospective customers of that industry, and public officials all agree that the present legislation is adequate for development and safeguarding such investments. Why should we, therefore, stand marking time industrially simply because the federal agency which must handle these matters is tied hand and foot for want of a paltry few thousand dollars and is compelled to work only with borrowed help? We understand that the House rules prevent immediate consideration of this measure; but it seems likely that if the chairman of the Rules Committee were sufficiently impressed with the importance of action at this session of Congress the necessary steps could be taken to insure it. We suggest this procedure to those concerned in early water-power development.

The Language Of Chemistry

THE language of chemistry has never been noted for its beauty. The main thing has been to get the ideas over, and if we have occasionally cracked an ear drum or split a tongue in the process, we haven't bothered about it. We haven't cared much about the style of our speech, and this very neglect has given the single-track humanists an effective club against science as a subject for study. Sometimes in our acceptance of "any old word" to carry a meaning we have wandered over into the field of the ridiculous, as when we adopt the phonetically Latinized word potassium from potash.

Occasionally an effort is made to shorten a word, such as the change from aluminium to aluminum. The late Dr. ROEBER would not have it, and so long as he lived this journal held to aluminium. Of late, so general has the shorter term become that, by some kind of linguistic mass action, it has broken through. And yet, in the names of elements, we hardly see reasons for the beginning of reform. We are not at all anxious to leave the i's out, even though it is a nuisance to dot them; we do not care for barum or cadmum or chromum or helum or magnesum or radum or selenium or any of the shortened forms. They're not enough better to spend the effort in making the changes.

There are, however, words that have served their usefulness, but which should give way to expressions of greater intrinsic merit. There is *specificity*, for instance, that sounds as if it had originated with a snake; it is a hissing noise, and although it finds greater use in biology than in chemistry, we are all guilty of using it occasionally. Whenever we do so we disturb the air and wound the language. Specificness is a better word and less offensive, although as an achievement in phonetics it is not a thing of beauty. The terminations *ition* and *ation*, when used too frequently, are no less than hurdles to good style in English. Those who practice the science of chemistry have the obligation to clothe their thoughts in an acceptable manner. When we say, "After crystallization and filtration the utilization of the filtrate is recommended for lixiviation until saturation is reached," we are clothing our thoughts in a manner of which we have good reason to be ashamed. We should not want to be responsible for such a sentence if it were to be carved in stone for

future generations to read. But, just as we form our habits of speech, so we shall speak. And if we want chemistry to have premerit in the thoughts of men we must use better language than that.

There are two words in everyday use that are no less than stutters, tongue-traps, and so difficult to pronounce that their very awkwardness keeps them out of use where they are most needed. We refer to the words qualitative and quantitative. Ever since the days of ROBERT BOYLE chemists of a philosophical turn of mind have been preaching the gospel of quantitative thinking, which humanity needs today more than ever it did before. But the word has been such a stumbling block that the layman has refused to utter it. And by this negation he has made the thought itself unwelcome. That extra syllable comes from the Latin declension *quantitas*, *quantitatis*, etc., but usage has provided that when a Latin declension stands in the way of good English, English that does its work in the clearest and most direct way, it should be avoided. And there are two words that mean exactly the same, that have been established in the language but allowed to become obsolete by mere neglect, and yet they may be found in dictionaries. These are *qualitive* and *quantitive*. They are more easily said, and are not phonetic offenses, such as their longer synonyms. We suggest the use of the adjectives qualitive and quantitive in the place of qualitative and quantitative. The entire subject is open to our readers for discussion.

Research, a Capital Investment Or an Operating Expense?

PURCHASE of a new machine or construction of a new building as a part of the equipment of any chemical industry represents capital expenditure, and is a physical investment on which earnings are expected and which must be gradually written off as depreciation or obsolescence may require. In public utility valuation there is added to the value of such physical property a certain sum known as "going value" to represent the intangible increase in the proper capitalization of the corporation because it is an active going concern organized and doing business instead of simply a total of machinery, material and structures.

The chemical executive in analyzing research costs can profitably take account of somewhat similar factors. A research organization well conceived and properly developed represents a real investment. The organization and training of the staff, its familiarity with the needs of the industry and its prospective invention or development output are all intangible, but are very genuine matters of value to the concern as a whole. In the present industrial circumstances, while costs must be cut to fit new conditions, it is of greatest importance that the executive should not unwittingly destroy the investment in his research department.

There are certain parts of the work that may perhaps profitably be laid aside for a time. There are doubtless misfits in the personnel which have resulted from the difficulty in getting adequately-trained men during the war period. There may even be some cases where valuable research men have outlived their usefulness to the particular situation in which they are now working. In any of these circumstances careful analysis of the coming year's budgets will justify some retrenchment. On the other hand, there are today available for engagement in new positions a greater number of ex-

perienced and promising research workers than ever before in the history of American chemical industry. It is an ideal time to make a little additional investment of capital in building up the research departments. Any concern which expects to continue to do business for many years to come can well afford to buy, in the present very favorable market, the services of some of these men. Even though the results of their labor may not be apparent for months or perhaps years, the investment can be made now to great advantage. It is unlikely that another season will pass leaving so many of these men who are really worth while open to new engagements. Immediate action will, therefore, be most expedient.

A Fool and His Money

ELSEWHERE we print a true report of the visit of a gentleman to see a demonstration of what was alleged to be a remarkable discovery. We are not allowed to give the name of the so-called "inventor" or the location of the hopeful plant, lest the credulity of certain underwriters be brought to light. We are glad, however, to give it such publicity as we may.

It is surprising how assertions in chemistry affect the lay mind. Analysis is supposed to be a rule-of-thumb procedure; it would almost seem as though the chemist had only to pour some of any substance into his mystic apparatus, and straightway not only every element but every chemical body would proceed under orders to some compartment marked out for it and then ring a bell. Of course if all the elements present go each to its respective cell and the compounds do likewise, it would seem that the compounds might be disturbed in the process, but, as the lay mind would declare, "You can't expect me to know about that," or, what would be more likely, "I haven't the *time* to look up that sort of thing."

Another curious disposition of the lay mind is to hurry in and buy stock before anyone with understanding comes along and condemns it. There was the electric refining of sugar that we remember about thirty-five years ago or more. The happy inventor made just such a demonstration; he put raw sugar into one end of the apparatus on the top floor, started his motors going, and in a few minutes beautiful white refined sugar swished down into a bin on the ground floor. It had the American Sugar Refining Co., which had lately been organized, beaten to a frazzle. The trouble was that after the inventor was called away to parts unknown, it was discovered that the raw sugar was deposited into an unseen bin, while the refined sugar was dumped out of another.

Everyone remembers the Reverend JERGUSON's fortune made by his process to extract gold from sea-water and the abundant proceeds he took away with him. Still another who got away with the money was the inventor of gold from goldfish. He flourished in New York, put his goldfish into an apparatus—and showed beads of gold as the product. Sober, solid business men who knew how to make fortunes and to keep them—until the chemical troubadour came along—closed their eyes and got into the ground waters with the goldfish! Only the other day in Berlin the cheerful Mr. UNRUHE came pretty near to getting a million pounds sterling for developing powerful electric currents from the hidden wires connected up with a central station. The method is monotonous.

British Chemical Industry

FROM OUR LONDON CORRESPONDENT

LONDON, Jan. 12, 1921.

CHEMICAL markets are still stagnant and very little business is passing either for home or export account. There is a nervous tone in both buying and selling, values being merely an indication of prices at which sellers are willing to sell or buyers willing to buy. Until the present abnormal conditions change business is too speculative and will be on a hand-to-mouth basis until the curve of values tends to straighten. Coal is again a disturbing factor on account of the serious effect of the slump in export prices due to incipient overproduction. An increase in the price of industrial and household coal is not improbable on account of the altered conditions in the trade.

CHEMICAL ENGINEERING GROUP PUBLISHES FIRST PROCEEDINGS

The first volume, embodying conferences on power plant and pumping machinery for chemical works, has at last been issued after unfortunate and vexatious delays. In sending out this volume the Group states that the second volume, dealing with labor-saving devices and filtration, may be expected in March and that the record of the meetings of the Group will not in future be published *in extenso* in any periodical other than the Group's *Proceedings*. The first volume is attractive and marks the beginning of regular and undiluted chemical engineering literature in this country. The conferences contemplated during the present year are to deal with plant for the treatment of industrial waste and evaporation and distillation. Recent papers read before the London Section of the Society of Chemical Industry dealt for the first time with the Smith (American) system of low-temperature carbonization and with the absorption of alcohol, ether, acetone, etc., by means of cresol. The last-named process was successfully operated during the war on a large scale by the Bregeat process both in this country and in France, and the results obtained should be of far-reaching importance for peace production of explosives and allied products.

POSITION OF INTERMEDIATES UNDER THE NEW DYESTUFFS BILL

The dyestuffs (import regulation) bill was passed on Dec. 23 and comes into force on Jan. 15. Literally it scraped through Parliament by the skin of its teeth, its supporters in the House of Commons having to fight throughout against time, and on two occasions the bill was nearly lost. The opposition in the House of Lords was even more effective and not of the same obstructive nature in that it was based on technical knowledge. Some of the amendments suggested in the House of Lords could have been embodied in the bill without much detriment, but if the bill had been so amended it would have had to go back to the House of Commons and could not have been passed during the current session. It is understood that one of the amendments proposed to exclude from the operation of the bill all intermediates which were not derived from coal tar and the bill was saved only by the giving of a parliamentary pledge to this effect, which will, of course, have far-reaching results if and when a list of such intermediates is formulated. A further amendment proposed to exclude "synthetic organic products imported mainly for medi-

cal or surgical purposes," and the mere fact of such a proposal being made does not augur well for the prospects of such protection as may ultimately be afforded to the fine chemical industry. It was understood at one time that acetic acid would also come under this bill in order to assist the Canadian synthetic industry, which is at present being strangled partly by the American import duty, but mainly by German competition. The Eastern markets have already been largely captured by the Germans and in view of the pledge referred to above the outlook is serious.

THE FINE CHEMICAL INDUSTRY IN EXTREMIS

When the campaign in favor of dyestuffs was started it was generally understood that provision would at the same time be made for the fine chemical industry, as being closely related and intimately connected with the dyestuffs industry both in regard to the linking up of manufacturing processes and in regard to the secondary object of maintaining an adequate force of trained organic chemists and potential auxiliary arsenals for chemical warfare and munitions manufacture. The last-named object has been greatly exaggerated in order to give emphasis to the movement and as the campaign progressed it was soon found that the opposition to immediate protection of the fine chemical industry would be so great as to endanger the passing of the dyestuffs bill as well. The lesser of two evils was therefore chosen and fine chemicals will now have to wait for protection until they can be included in an "omnibus" key industries bill in the next parliamentary session. Meanwhile the industry is practically stagnant, and when the key industries bill comes up for discussion it is certain to be of such a contentious nature that grave doubts are expressed as to whether the fine chemical industry can be saved unless a separate and non-contentious bill can be introduced for this industry alone. That, of course, requires time and money, which do not seem to be available at present. Perhaps the chief factors which have led to the present critical position of the industry are lack of confidence in the government and the notorious failure of the manufacturers themselves to translate their talk of co-operation and community of interest into actual practice. The question has already been asked of the dye industry whether, having received protection, it will be able to supply the right dyes, and those best qualified to judge are more pessimistic in this connection than in regard to the fine chemical industry, for which there is at present insufficient capital available.

FORMATION OF A BRITISH CHEMICAL PLANT ASSOCIATION

The Association of British Chemical Manufacturers is the sponsor of an association which has for its main object that British chemicals shall be made with British plant. It cannot be said that the members appointed to the positions on the first committee are such as to inspire complete confidence in the attainment of this object, and representatives of the chemical stoneware makers and other important manufacturers are conspicuous by their absence. It is understood that the movement is to some extent bound up with the question of standardization of detail fittings and items of plant, which has at last, after considerable discussion, been set in motion by the formation of a chemical engineering sectional committee of the British Engineering Standards Association.

Chemical Properties and Metallography of Nickel

Data on Solubility and Magnetic Transformation of Pure Nickel—Notes Are Also Given on the Effect of the Common Impurities Such as Carbon, Oxygen, Manganese, Sulphur, Cobalt, Iron and Silicon Upon Various Physical Properties

BY PAUL D. MERICA

Superintendent of Research, International Nickel Co.

NICKEL is not an active element chemically. It is not attacked at ordinary temperatures by air, fresh or sea water or combinations of the two. Organic acids such as acetic, oxalic, tartaric and citric acids attack it appreciably only after long periods of contact. Sulphuric and hydrochloric acids dissolve it slowly; in nitric acid, on the other hand, it is very readily dissolved. Alkalis either in the fused state or in solution in water are without effect upon it, and for this reason, laboratory fusions with these substances are carried out in crucibles of this metal.

SOLUBILITY

At temperatures around 500 deg. C. it becomes oxidized in the air and also decomposes water with formation of hydrogen.

Hale and Foster have measured the dissolution of nickel sheet in various solutions at ordinary tempera-

TABLE I. CORROSION TESTS OF NICKEL

Specimens Immersed in:	Loss of Weight in 7 Days (Solution Renewed Daily), Grams	Loss of Weight in 28 Days (Solution Not Renewed), Grams
HNO ₃ (N/5).....	4.2	2.1
HCl (N/5).....	0.25	0.45
H ₂ SO ₄ (N/5).....	0.25	0.40
MgCl ₂ (N/5).....	0.05	0.10
NaOH (N/5).....	0.00	0.00
CaCl ₂ (N/5).....	0.08	0.05

Na ₂ CO ₃	0.00	0.00

ture¹ and their results expressed in loss of weight per 100 sq.cm. are given in Table I.

Nickel is used for cooking utensils quite extensively in Germany and this has inspired numerous investigators to study the question of the solution of nickel by the liquids used and its absorption by the food, as well as the physiological effect of the amounts thus absorbed.² The results of these investigations have usually been expressed in terms of milligrams of nickel found in 100 g. of the food and varied from 0.01 mg. to a maximum of 64 mg., the high results being obtained by the use of salt and vinegar or food containing both. Vuk³ found losses of from 15 to 65 mg. of nickel per sq.m. of exposed surface after boiling in 5 per cent acetic acid for 2½ hours. These small amounts of nickel thus absorbed by food from nickel utensils have been regarded as being entirely harmless physiologically.

The heats of formation of two of the more important compounds of nickel are given by Richards⁴ as:

NiO61,500 gram-calories
NiS19,500 gram-calories

Sieverts⁵ has determined the solubility of hydrogen in nickel and finds that it forms a homogeneous solid solution. The solubility of hydrogen both in solid and in molten nickel is proportional to the square root of the hydrogen pressure. He found that 100 g. of nickel absorbs, at 760 mm. pressure:

0.16 mg. H at 212 deg. C.
0.39 mg. H at 520 deg. C.
0.98 mg. H at 1,023 deg. C.
1.50 mg. H at 1,400 deg. C.

and that this amount liberates 1.9 mg. hydrogen upon solidification at 1,452 deg. C. in a hydrogen atmosphere of 760 mm. pressure.

METALLOGRAPHY

As far as is known, nickel exists in only one solid modification or phase which is stable at all temperatures up to that of its melting point. It suffers, however, a magnetic transformation, in a manner quite similar to iron, at about 360 deg. C.; below this temperature it is ferromagnetic, above, it is only weakly paramagnetic. Values of the temperature of this transformation varying from 320 to 370 deg. C. have been obtained by different investigators working with nickel of different degrees of purity, and are shown in Table II. There is therefore some uncertainty about the exact temperature of this transformation, and the value accepted above represents the results of those who worked with the purest material. The magnetic transformation of nickel, as in the case of iron, is accompanied by changes in the other physical properties such as density, resistivity and thermo-electromotive force.

As the magnetic transformation of nickel is not accompanied by any determinable alteration in structure

TABLE II. TEMPERATURE OF THE MAGNETIC TRANSFORMATION OF NICKEL

Authority	Chemical Composition				Temp. of Transformation, Deg. C.

found in commercial nickel are with three exceptions soluble in the solid state in the amounts in which they are usually present—namely, iron, copper, manganese, cobalt and silicon. Nickel oxide, sulphides (of nickel or manganese) and carbon are at times visible as separate constituents in nickel. In addition there may be found in all malleable nickel a small amount of magnesium compounds in the form of small round particles.

Fig. 1 shows the structure of commercial nickel blocks and the appearance of the nickel:nickel oxide eutectic. This is found, of course, only in non-malleable nickel, as it is impossible to work the metal containing it at any temperature. The structure of malleable nickel in the form of hot-rolled rod is shown in Fig. 2; only the grains of nickel and the small particles of magnesium (and possibly manganese) oxides are visible. Carbon is soluble in nickel to about 0.40 per cent and is therefore not ordinarily observed in commercial nickel. Above that percentage, however, it begins to separate out in the form of graphite; Fig. 3 shows the appearance of graphite in rolled nickel.

Nickel is subject to a peculiar type of intercrystal-

solutions appear to give more uniform results than the aqueous solution, in which the metal readily assumes the passive state.

Electrolytic etching is also recommended, an electrolyte of sulphuric acid and hydrogen peroxide being used as follows: 22 per cent sulphuric acid, 12 per cent hydrogen peroxide solution, 66 per cent water.

EFFECT OF IMPURITIES ON THE PROPERTIES OF NICKEL

With reference to the effect which they exert upon the physical properties of nickel the ordinary impurities fall naturally into two classes—i.e., those which are soluble in the solid state in nickel and those which are not. Those of the former class act in general only to increase the hardness and strength of the metal somewhat, and of course to diminish its electrical conductivity. Those of the latter class affect chiefly the hot-but also cold-working properties of the metal.

Carbon.—Carbon is hardly to be looked upon as an impurity in nickel any more than it is to be so regarded in steel; it is an element which is never absent in the metal and its presence is in the present state of the art

Fig. 1. Microstructure of nickel blocks showing nickel:nickel-oxide eutectic. $\times 100$.

line brittleness which has been structurally well described by Rawdon and Krynitzky¹³. When exposed at high temperatures (i.e., from 1,000 to 1,200 deg. C.) to the action of oxidizing or sulphurizing gases the boundaries of the surface grains are attacked, either oxidized or sulphurized, and the cohesion between the grains is destroyed. These surface layers become quite brittle and will not elongate or flow under subsequent drawing or rolling operations, but there is produced a network of fine cracks on the surface under such treatment. The presence of these cracks indicates a faulty heating operation—i.e., either the flame was too oxidizing and “burnt” the metal, or it introduced sulphur into it. Fig. 4 shows the structure of such “heat-checked” nickel sheet.

The best etching agent is nitric acid, and for that purpose a volume concentration from 75 to 100 per cent acid may be used. Somewhat better results may be obtained by using a solution of nitric acid of a volume concentration of from 50 to 75 per cent made up by diluting the concentrated acid with a 50 per cent aqueous solution of glacial acetic acid; these acetic acid

necessary for the commercial production of malleable nickel.

The nickel-carbon equilibrium diagram has received some attention at the hands of investigators, but there are still many gaps in our knowledge of the constitution of this binary system. With increasing carbon content the melting point of pure nickel is progressively lowered from 1,452 deg. C. to 1,311 deg. C., at which temperature nickel forms a eutectic with 2.2 per cent graphitic carbon. The liquidus temperature then rises again with increasing carbon content and at 2,100 deg. C. the metal absorbs 6.42 per cent carbon, apparently in the form of a carbide, Ni_3C^{14} , which is, however, rapidly decomposed at lower temperatures with formation of graphite. The equilibrium below the eutectic temperature has never been satisfactorily worked out. Ruff, Borman and Keilig¹⁵ state from the results of their investigations that the solubility of graphite in nickel in the solid state is not greater than 0.5 per cent at the eutectic temperature, but they give no information about the presumably diminishing solubility at lower tempera-

¹⁴W. Borman, Dissertation, Techn. Hochschule, Danzig, 1915.

¹⁵Z. anorg. allgem. Chem., vol. 88, p. 386 (1914).

tures. Although we do not have the exact knowledge of equilibrium at lower temperatures which would be desirable, it is known that the presence of carbon introduces no transformation such as that which occurs in steel, and with which might be associated the possibility of profoundly altering the physical properties of the alloy by means of a suitable heat-treatment.

Within the limits of composition within which carbon is usually found in nickel it occurs in solid solution and merely increases the hardness and strength of the metal. It increases the ease of hot-working operations by making the metal tougher at these temperatures and less susceptible to edge cracking. On the other hand, it increases the difficulties of cold-working both because with increased carbon the metal is initially harder and also because it hardens more rapidly with progressive cold work. The effect of carbon in increasing the hardness of nickel is illustrated in Table III.

When the percentage of carbon exceeds about 0.40 per cent the separation of graphite may take place, which is accompanied by a loss of malleability. Free graphite should not be present in good quality malleable nickel. The statement that carbon is harmful to malleable nickel

TABLE III. EFFECT OF CARBON ON THE HARDNESS AND TENSILE STRENGTH OF NICKEL

Chemical Composition					Tensile Properties				Hardness		Remarks
C	Mn	Si	S	Fe	Yield Point	Tensile Strength	Elongation in 2 In.	Reduction of Area	Brinell 3000 Kg.	Scler scope	
0.08	...	0.04	0.026	0.63	22,000	69,000	46	50	103	10	Hot-rolled
0.26	0.48	0.13	0.016	0.56	34,000	93,000	40	35	132	17	Hot-rolled
0.19	0.26	0.33		0.68			..	..	131	15	Annealed
0.06	0.21	0.33		0.59			..	..	97	10	Annealed

and that its presence should be avoided is not correct, but applies when the carbon is in form of graphite.

Nickel Oxide (NiO).—This compound cannot be present in malleable nickel and is therefore in a sense not to be regarded as an impurity in it; on the other hand, its potential effect on the properties of the metal make necessary certain procedure in the preparation and de-oxidation of malleable nickel of the utmost importance. It does occur in shot and casting blocks and occasions the complete lack of malleability of these forms of the metal.

The equilibrium of nickel and nickel oxide has not been systematically studied. The only mention of it is by Ruer and Kaneko,¹⁴ who state that the presence of NiO in molten nickel depresses the melting point by about 10 deg. C. and they give a photomicrograph showing the eutectic structure of it in nickel. Apparently nickel dissolves several per cent of nickel oxide in the liquid state, but it is completely insoluble in the solid state and separates out in the form of a eutectic. Fig. 1 shows the appearance of this eutectic in nickel blocks.

As nickel oxide is always found and is probably always formed in refining molten nickel, it is necessary to remove it before pouring the metal into ingots for forging or rolling. This may be done by means of manganese, aluminum or magnesium, but the latter element is by far the best and is most generally used. It is introduced in the form of a 1- to 2-in. rod either into the crucible or the teeming ladle; it must be plunged to the bottom and stirred around briskly in

order that it will not merely float to the surface and burn off. Approximately 1.5 oz. to the hundred pounds of metal is added; more magnesium will do positive harm, making the melted metal thick and sluggish to pour.

Manganese.—Manganese is generally absent from non-malleable nickel, but is added intentionally to malleable metal both because of its effect on its ultimate properties and because of its usefulness in decreasing manufacturing difficulties. It renders the metal less tender just after freezing and thus aids in the production of ingots free from "pulls" and hot cracks. It

Fig. 4. Microstructure of cross-section of heat-checked nickel sheet, showing intercrystalline oxidation of surface layers.

also increases the fluidity of the molten nickel and thus renders easier the production of ingots of good surface.

These advantages are obtained with small additions. Added in larger amounts, it increases the resistance to oxidation and renders it less susceptible to the action of sulphur in the fuels used in hot rolling. Thus it is the C and D grades of nickel, containing from 1.50 to 6 per cent manganese, which are largely used for the spark points of motor ignition systems.

The equilibrium of the system manganese:nickel has been studied by Zemczuzny, Urasow and Rykowskoff,¹⁵ who find that the two metals are soluble in all proportions both in the solid and in the liquid state. This agrees with our rather meager knowledge of the properties of high manganese:nickel alloys. These may be rolled readily up to 10 per cent of manganese and prob-

TABLE IV. EFFECT OF MANGANESE ON THE PHYSICAL PROPERTIES OF HOT-ROLLED NICKEL ROD

No.	Chemical Composition					Tensile Properties					
	C	Mn	Fe	Si	S	Proportional Limit	Yield Point	Tensile Strength	Elongation in 2 In.	Reduction of Area	Electrical Resistivity, Microhm-Cm.

ably beyond, although the 50 per cent alloy is known to be quite brittle. Within these limits the addition of manganese mildly increases the hardness and strength of nickel without materially decreasing the ductility.

¹⁴Metallurgie, vol. 9, p. 419 (1912).

¹⁵Z. anorg. allgem. Chem., vol. 57, p. 263 (1908).

The addition of manganese, however, does decrease the electrical conductivity of nickel markedly;¹⁸ thus the resistivity of nickel, drawn and annealed, was increased from 12.43 microhm-cm. to 28.0 and 51.2 microhm-cm. with the addition of 10 and of 20 per cent respectively of manganese. Table IV shows the effect of manganese on the tensile properties and resistivity of hot-rolled nickel rod.

Sulphur.—The form in which the usual small amounts of sulphur occur in commercial nickel is not known, but it is present presumably as a sulphide of nickel or of manganese. Its presence in amounts above 0.05 per cent decreases the ductility both hot and cold and it should be held as low as possible in nickel intended for malleable ingots.

Judging therefore by its effect on the properties, it is present in the form of a separate constituent, insoluble in the solid state in nickel. Bornemann¹⁹ has investigated the equilibrium of the system nickel: sulphur and finds that a compound is formed, Ni_3S_2 , which is soluble in the liquid state in nickel but which forms a eutectic with it at 21.5 per cent sulphur and 644 deg. C. upon freezing. The solubility of Ni_3S_2 in nickel in the solid state at the eutectic temperature is about 0.5 per cent and rapidly approaches zero at lower temperatures.

Iron.—This element is always present in commercial nickel due both to imperfect removal of the iron originally present in the ores and to the wear and solution of tools used in the roasting and refining furnaces. The amount present is usually less than 1 per cent and has no appreciable effect upon the properties of the metal. The system nickel:iron has been investigated by Guertler and Tammann,²⁰ Ruer and Schuz²¹ and others, who find that the metals form an uninterrupted series of solid solutions, with certain interesting anomalies to be described later in an article in this series entitled "Iron:Nickel Alloys."

Cobalt.—This element in amounts up to 1 per cent and averaging about 0.3 per cent in American nickel is invariably found in nickel and is usually included in the figure given for the nickel content. It is soluble in the nickel in all proportions both in the liquid and in the solid state and in small amounts does not exert any appreciable effect upon the properties of nickel except probably the electrical resistivity.

Silicon.—According to Guertler and Tammann,²² this element forms a compound, Ni_3Si , with nickel which is soluble in molten nickel, but upon solidifying forms a eutectic with it at 10.6 per cent silicon and 1,153 deg. C. The solubility of this compound in the solid state in nickel is equivalent to 6 per cent of silicon at the eutectic temperature, decreasing to 2.5 per cent at 660 deg. C. and approaching lower values as the temperature decreases.

Silicon is always present in furnace-refined nickel in amounts generally under 0.25 per cent and has comparatively little effect. In larger amounts the hardness of the metal is increased and its ductility decreased and with still increasing amounts the malleability, both hot and cold, is diminished and finally destroyed completely. This occurs at a content of about 3 to 5 per cent of silicon.

Oil Refinery at Swansea Near Completion

The new oil refinery of the Anglo-Persian Oil Co. at Swansea is now practically ready to begin operations, reports Consul Cooke. The company states that it expects to begin refining oil in February or March, 1921. The refineries are located at the village of Skewen, about four miles from the port of Swansea, among the hills. The company has leased from the Swansea Harbor Trust on long lease fifty acres of land lying adjacent to the King's Dock, where there have been erected four huge sheet-iron tanks with a capacity of 2,500,000 gal. each. These tanks are connected with the adjacent dock and jetty by underground pipes. It is proposed to use three of these tanks for storing the crude oil as it is piped from the discharging vessel, and from these the oil will be pumped up to the refineries. The fourth tank is to receive the refined oil, which will return from the refineries by gravity and be delivered by pipe to receiving vessels as they lie alongside the jetty.

The initial capacity of the plant is stated to be 12,000 to 15,000 tons of oil per week. The capacity, it is expected, will be doubled within two years. The crude oil will be brought in bulk from the Persian fields and from other sources as they are available.

Every precaution has been taken to facilitate the shipping of oil by vessels whether for bunker or cargo. To this end the company has laid down pipes from the tank to the jetty, thus obviating the necessity of vessels entering the King's Dock. They have only to take berth alongside the jetty, and the oil will be supplied to them through pipes.

While the primary object of the company is to refine for fuel purposes, it plans ultimately to enter the field of high-test refining and to turn out both oil for lighting and gasoline.

Steel From Japanese Iron Oxide Sand

A method whereby iron may be smelted from the volcanic iron oxide sand of Japan, heretofore regarded as wholly refractory, is said to have been discovered by scientific experimenters working for the War Department of that country. While the discovery cannot be employed as yet commercially, the cost of the iron so obtained being too high to compete with iron smelted from ore, the value, from a military standpoint, of the process to Japan, which, like every other volcanic country, is rich in deposits of iron oxides, is regarded as being great, inasmuch as it may place that country in an independent position so far as its supply of steel for military and naval uses, where cost is not the deciding factor, is concerned.

A statement made by the War Office on Oct. 18 said, with regard to the process, which is being guarded as a military secret: "Iron sand is so general throughout the entire length and breadth of the empire that it has long been plain that if some method were discovered of smelting the iron from it, Japan would never suffer from want of steel. On the strength of the above, the necessary investigations were started as early as September last year by a special committee, with experimental offices established in the Aomori Prefecture, and with Dr. Kishi as chief engineer. The experiments of a year have now been crowned with tolerable success, and the process has been experimented with on a practical scale at the Penchihi works under the control of the Okura firm with very satisfactory results."—*The Engineer*, Dec. 24, 1920.

Salt Manufacture in Michigan

Description and Technology of the Salt Deposits of Michigan—Preliminary Treatment, Storage and Settling Tanks—Salt Grainer and Vacuum Pan Operation—Mechanical Crystal Handling Devices—Types of Crystals Produced

By W. L. BADGER

VERY little has been published on the engineering features of salt manufacture. The few articles that have been published are mainly in publications not usually consulted by engineers.¹ One well known handbook has a description that gives an entirely false impression of the present state of the industry. This paper describes present practice as it is found in the eastern district of Michigan, which is now the principal salt-producing field of the United States.

SALT DEPOSITS

The geology of salt deposits in Michigan has been reported in several places.² The lower peninsula of Michigan is a syncline or basin. There are several salt-bearing strata, but the most important one is the Salina. This is at a depth of 700 to 1,200 ft. in the neighborhood of Detroit and dips rapidly to the north and west. It is found at a depth of about 1,600 ft. in the vicinity of St. Clair, sixty miles north of Detroit. In the center of the state it is too deep to work, but it reappears in the northwest corner of the lower peninsula in the vicinity of Ludington and Manistee. Here it is at a depth of 1,900 to 2,200 ft. The salt varies in thickness. Sometimes there are several thin seams, some more or less impure. In other places, especially along the Detroit and St. Clair Rivers, the main bed is from 100 to 400 ft. thick and very pure, although there are thin seams of impure salt above it. In the Saginaw Valley, on the other hand, the source of salt is natural brine. This is found in the Parma and Napoleon formations. The Parma is just below the coal horizon in Michigan, and the Napoleon a little lower. Brine is met at a depth of only 700 to

850 ft., but it is more impure than the salt of the Salina deposit. It is high in calcium and magnesium chlorides, and contains enough bromides to be the basis of the most important bromine-producing district in the United States.

Salt production in Michigan can be divided, then, into three quite distinct districts: the Detroit and St. Clair River District; the Saginaw Valley district; and the Ludington-Manistee district. This paper is concerned mainly with the present practice in the first of these districts.

SOURCE OF BRINE AND PRELIMINARY TREATMENT

The main bed of the Salina formation is usually pure enough to work up into high-grade salt with little preliminary treatment. Since the deposit is rock salt, an artificial brine has to be made by pumping down river water. A typical log of a well is shown in Fig. 1. This well is at the plant of the Worcester Salt Co. at Ecorse, just south of Detroit. The outer casing is continuous to the top of the first bed of salt worked. From this point the well is 6 in. in diameter, uncased, to the bottom of salt. A central line of tubing goes to the bottom of the well. Practice is not uniform as to pumping; wells are usually supplied with water through the annular space and the brine flows up through the central tubing. Perhaps the less common case is where water is supplied to the bottom of the well through the central tube.

If the cavity at the bottom of the well is closed, no air need be used; and the pump which delivers water furnishes pressure for raising brine. In some cases two or more wells become connected at the bottom. In this case water may be pumped in one well and brine obtained from the other; or each may be pumped by air lifts. At one of the older plants an estimate was made of the size of the cavity. Assuming that water pumped down was distributed uniformly over the cavity and worked down to the outlet uniformly, the time elapsed between pumping in water and getting out the same water as brine was about three years.

When several beds are worked as in Fig. 1, at intervals the shale strata between the salt strata cave in and block the well so that the wells have to be redrilled occasionally. Where the wells work only one thick bed, they seldom need any attention for long periods.

This method of working gives a fully saturated brine. Brine is usually reported in salinometer degrees—i.e., on a scale where 100 deg. is a completely saturated brine. No plant in the Detroit district expects to work on less than a 99 deg. brine, and it is usually 100 deg.

These brines are so pure that the usual preliminary treatment is merely settling. There is a plain odor of hydrogen sulphide in the brine as it comes from the wells. There is usually little or no iron present—so little in most cases that direct tests without concentration usually fail to show iron.

FIG. 1. LOG OF WELL

SETTLING TANKS AND GRAINERS

The old-time salt maker used to say that good salt could not be made from brine less than twenty-one days old. It is difficult to

place the reason for this superstition. Some plants still think they can get better salt by settling the brine, but in most cases the settling tanks are merely to give storage capacity; and, if necessary, brine goes from the wells directly to evaporators or grainers with no apparent lowering of the quality of the salt made. Very few plants in the eastern Michigan district have capacity for more than

FIG. 2. TIMBER TANK CONSTRUCTION

twelve or eighteen hours' supply of brine. One of the most characteristic features of salt plants in this district is the old wood settling tank. Most of these plants were built long enough ago so that timber construction was the cheapest for settlers. Also, complete avoidance of iron made it easier to get a good-colored product. The method of bracing and tying these storage tanks, without the use of any iron, is very interesting. Buckstaves 3 x 10 in. on about 30-in. centers pass through mortises in 8 x 10-in. sills below and 6 x 10-in. ties above. By means of a pin and wedges the tank is tied crosswise and the side planks are drawn down. The planks are not tongued. A diagrammatic sketch appears in Fig. 2, and photographs of this style of construction are shown in Figs. 3 and 4.

These tanks are usually about 150 ft. long, 15 ft. wide and 6 ft. deep. They are divided by cross-bulkheads into individual sections about 50 ft. long. The commonest construction is to build sets of two tiers with two long tanks in each tier. Brine from the wells is discharged into launders running over the tanks. If the brine is to be limed, hydrated lime is made into a thin milk and scattered over the surface of the brine after the tank is filled. Some plants use no lime at all, others very little. Probably the maximum amount used in this district is 50 lb. hydrated lime for one tank 50 x 15 x 6

ft. This amount is considered excessive at other plants. The grainer is a typical Michigan institution. It developed in the early days of the salt industry when salt was almost wholly a byproduct made by waste steam which was generated from saw-mill refuse. It is an inefficient and crude device; but it makes a characteristic grade of salt for which

FIG. 3. TIMBER SETTLING TANKS

there is a definite demand. The usual form of grainer is a steel trough, 150 ft. long, 12 to 15 ft. wide and 22 in. deep. In it are hung steam pipes, and brine is evaporated without boiling. Grainers are usually of 1/4-in. plate, single lap riveted. Due to rapid corrosion of iron exposed to salt and air (iron completely immersed in brine corrodes much more slowly), all parts of a salt plant are made as simple and cheap as possible. The grainer shell rarely has a flange or stays, and coil hangers and similar parts are very simple.

In the old days grainers were made of wood, but there are comparatively few wood grainers now in existence. Willcox⁴ has described the construction of concrete grainers. These have proved entirely satisfactory in other districts but very few have been built along the Detroit and St. Clair Rivers.

Coils are of 3 1/2 or 4-in. pipe, and there are nine to thirteen passes in each grainer. In some grainers the pipes are in parallel from one header. In other cases they are arranged in two or three parallel coils. There

⁴G. B. Willcox, *loc. cit.*

FIG. 4. TIMBER SETTLING TANKS

³Loc. cit.

are occasional grainers in which all the turns of the heating surface are in series in one coil. Probably series-parallel arrangement is the commonest. The objection to straight parallel arrangement is that different pipes do not discharge their condensed water uniformly from a common header. One is apt to be water-bound while another is discharging, and this condition oscillates across the coils so that expansion and contraction strains are excessive. The coils are usually hung from crossbars which are either loose and resting across the edges of the grainer or riveted to the grainer walls.

Originally the salt was removed by hand. Now, mechanically raked grainers are universal. The rake used in practically all grainer plants is made by the Willcox Engineering Co. of Saginaw and is described briefly in the paper mentioned above. It consists of

FIG. 5. CROSS-SECTION OF GRAINER

a framework of angle iron submerged in the brine and worked back and forth by a hydraulic piston. Scrapers pass the salt to one end of the grainer, work it up on a drain board and over into the conveyor. Figs. 5, 6, 7 and 8 show this construction. The main frame of the rake is of 2 x 2 x 1/4-in. angle irons, in panels about 8 ft. long, with diagonal braces to each panel. On the transverse member of each panel are fastened scrapers of 1/4 x 6-in. plate, hung with cast iron hinges, as shown in Fig. 6.

This allows the scrapers to "feather" over the salt on the back stroke, and to engage the salt on the forward stroke. In Fig. 8 may be seen the scrapers with their diagonal braces. A 10-ft. stroke results in a progressive motion of the salt. Fig. 5 shows a cross-section of a grainer in which the coils are hung from cross-pipes riveted to the grainer walls. The rakes slide on short angles fastened at intervals along the grainer sides. Power for the rakes is furnished by a hydraulic cylinder. This is usually about 8-in. bore, and is supplied with water at from 60 to 100 lb. Reversal is accomplished by a trip rod, operated by a striker attached to the rake frame, actuating a linkage which throws a hydraulic reversing valve. Figs. 9 and 10 show the linkage used by the Willcox Engineering Co. in its installations. A trip rod from the grainer rake (3) has a yoke with rollers (5) bearing on the lever (1). At the end of a stroke of the rake, a striker on the grainer rake frame engages a collar on the trip rod and

FIG. 6.
GRAINER RAKE
AND SCRAPER

FIG. 7. EMPTY GRAINER

pulls the lever (1) over into the position shown by the dotted lines, thus throwing the hydraulic reversing valve whose stem is connected to (2). The valve, piping and trip mechanism are shown in Fig. 10.

Another linkage used in the plant of the Worcester Salt Co. is shown in Figs. 11 and 12. In Fig. 11 (5)

FIG. 8. GRAINER SHOWING
DETAILS OF RAKE

is the trip rod from the rake, and the stem of the hydraulic reversing valve is attached to the pin G. As the rake reaches the end of a stroke, it moves the trip rod (5) to the left, which rotates bar (2) around A and lifts the counterweight on rod (4). When pins D, E, A and B are in line the linkage is on a dead center, but the valve has not been moved because of the slot in bar (6). As pin E moves beyond this line the toggle is upset, the weight on bar (4)

falls and pulls the linkage into the position shown by the dotted lines, and the resulting motion of pin G operates the reversing valve.

The delivery end of the grainer is sloped up at an angle of about 30 deg. and the end panel of the rake is hinged so that salt is shoved up on this sloping drain board. The end scraper does not go to the edge of the drain board at the end of its stroke, but leaves enough space between the end of its stroke and the discharge to store several scraper-loads of salt. Thus the salt drains for some minutes before being pushed off into the conveyor below.

The speed of the rakes varies with the rate of evaporation in the grainer. When working near to capacity about one complete double stroke in two

the purity of the brine and the rate of operation. Few producers have any standard for purity of the salt, and hence have no standard for the concentration of impurities which may accumulate in the bittern before discarding. A table of analyses of grainer discard bitterns in Cook⁵ shows the following extreme cases, with the rest distributed anywhere between:

	Grams per Liter			Grams per Liter	
K	0.1	2.0	Mg	0.2	2.7
Na	121.1	104.6	Cl	187.5	194.6
Ca	1.9	13.8	SO ₃	3.4	0.6

Where calcium chloride is to be manufactured from the bitterns, a further evaporation removes most of the sodium chloride and gives a highly concentrated bittern to go to the calcium chloride evaporators proper. Sodium chloride is almost insoluble in strong solutions of calcium-magnesium chloride mixtures.

The capacity of a grainer is quite variable. It depends on the temperature and humidity of air circulating over the grainer, and on the wind or other conditions affecting air supply. The number of coils, steam pressure, amount of scale, and temperature of brine fed, all affect the capacity. A clean grainer and 40 lb. steam will result in about 140 to 150 bbl. of salt for one 12 x 150-ft. grainer per twenty-four hours. Atmospheric steam will give as low as 50 bbl. A fair average is 80 to 100 bbl. per day.

Grainer salt is almost never dried. It is usually conveyed to a storage building and allowed to stand in stock piles for varying lengths of time. Under the old state law for salt inspection, salt was not to be packed until it was twenty days old. This length of time is not now maintained, and salt is packed or shipped as soon as the moisture content is low enough. As there are almost never accurate specifications, this means that grainer salt is packed after a storage that depends on the relation between the amount in stock and the amount being sold. If it can be sold as fast as made, it is packed after the least storage—possibly less than a week—that will give salt dry enough to satisfy the buyer.

Salt is sold in standard barrels of 280 lb. net. Grainer salt may be packed in barrels or sold in bulk. It is rarely sold in packages smaller than a barrel.

One characteristic of sodium chloride, when formed by slow evaporation, is that it forms hopper-shaped crystals. These hoppers are composed of true cubes of the regular system united at their corners to form a hollow pyramid. Fig. 13 shows a characteristic hopper crystal, though the crystal photographed was ac-

tually KClO₃. These pyramids form at the surface of the brine in the grainer and float for some time. Chance drafts and disturbances send them to the bottom before they get very large. In rare instances they may be obtained as much as $\frac{1}{4}$ in. across. This slow surface evaporation, combined with the habit of sodium chloride to form crystal aggregates rather than large compact crystals, gives grainer salt its peculiar open structure which is the only reason for its existence. Photo-micrographs of grainer salt are given in Figs. 14 and 15. Grainer salt will dissolve faster than vacuum pan salt of the same grain size. Due to its open structure, it carries much mother liquor with it which is not drained out, but dries on the crystals. Hence it is never as pure as vacuum pan salt. Standards for color are not as rigid as for vacuum pan salt.

Grainer salt goes to various markets. Some is used for salting hides, though crushed rock salt is generally preferred for this. Some grainer salt goes for dairy purposes, some for ice cream manufacture. Much is sold to jobbers for miscellaneous uses, some jobbers drying it and packing it as a low-grade table salt for the cheaper trade. Undoubtedly much grainer salt is used for purposes where pan salt would be equally good, the demand for grainer salt being only a trade tradition.

VACUUM PAN PROCESS

The first single effect vacuum pans in Michigan were built about 1888 or 1889, and the first double effect pans in 1895. When this is contrasted with the sugar indus-

FIG. 16. VACUUM PAN SALT

⁵Loc. cit.

try, where the first vacuum pan was built in 1812 and the first multiple effect pan in 1845, it will be seen how little engineering attention has been given to salt manufacture. The obvious reason is that salt in Michigan has always been a byproduct of industries having large amounts of waste heat, so that questions of fuel economy never arose. About 20 per cent of the country's total salt production is now made in vacuum pans. In the Michigan districts the capacity for vacuum pan salt production is nearly equal to the grainer capacity.

In salt manufacture, double effects are common and triples are often met with. Quadruple effects are rather rare, due to excessive losses from the difference between the boiling point of salt solution and that of pure water under the same pressure. Without going into the theory of multiple effect evaporators, it may be said that this elevation of the boiling point of a solution is a total loss of available temperature drop in a multiple effect evaporator. This loss is repeated in every effect. As the working range of such evaporators is usually limited by conditions outside the designer's control, too many effects leave too little working temperature drop. Since capacity depends directly on the working temperature drop, attempts to increase economy, by increasing the number of effects, rapidly result in decreased capacity.

The standard form of evaporator is the usual vertical tube evaporator, with a central downtake. The tubes are usually from 4 ft. 6 in. to 5 ft. 6 in. long, and from $2\frac{1}{2}$ to 3 in. in diameter. A small salt pan will be 6 ft. in diameter and a large one 20 ft. Steam pressure, of course, varies, but multiple effects are seldom run on steam much above atmospheric pressure. Most plants succeed in maintaining a vacuum on the last effect better than 27 in. on a 30-in. barometer.

The central downtake varies in size, but is usually from 75 to 150 per cent of the total tube area. In pans built by the Manistee Iron Works, one of the best known builders of salt pans, there is a propeller in this downtake to aid circulation. Below the calandria is a conical bottom, the sides inclined 30 deg. or less to the vertical, and this cone is prolonged into a "salt leg" in case an elevator is used to remove the salt. The upper part of the body is also conical, sometimes having a belt sloped outward, just above the tube sheet, to prevent material caked on its sides falling into the salt below. Fig. 17 shows the essential features of a typical salt pan with its elevator.

Due to the universal presence of calcium sulphate in brines of this district, heating surfaces gradually become coated with sulphate scale. There is also the phenomenon of "salting up" which must be met. Most of the salt formed, as evaporation proceeds, forms as free crystals suspended in the solution. Gradually, however, a coating of salt crystals builds up on all hot surfaces just as scale forms. The cause of this difficulty is not definitely known, though each plant has a theory. In conjunction

with the presence of calcium sulphate scale, "salting" helps to make the deposit on the tubes grow more rapidly. Consequently most salt pans have to be boiled out with water or dilute brine at intervals; and at longer intervals the pan must be shut down and calcium sulphate scale drilled out.

One method is to have vapor lines so arranged as to permit cutting out one body for cleaning while the rest are operating. The three pans of the Worcester Salt Co. are so arranged that all three can be run as a triple effect, or any two as a double effect, or any one as a single effect. They are generally operated as a double, one after the other being cut out for cleaning. The pan used as a first effect will be boiled every ten to fourteen hours; the second effect every twenty to thirty hours. The three pans of the Canadian Salt Co. at Windsor, Ont., are arranged as two first effects and one second effect. One first effect is cleaned each day, and the second effect once a week. The three pans of the Inland-Delray Salt Co. in Detroit are arranged as a straight triple effect. They are boiled Wednesday each week by letting the brine down a couple of feet and filling with water to the former level. This dissolves out salt that has formed by "salting." On Saturday the whole evaporator is shut down and drilled. In most cases pans are drilled often enough to prevent much more than $\frac{1}{8}$ in. of calcium sulphate, though there may be a good deal of salt on top of this.

The capacity of a vacuum pan depends on many factors, and few operators have exact data on the capacity of their equipment. Steam pressure, amount of scale and salt on the tubes, brine level and many other factors enter into a statement of capacity.

REMOVING THE SALT

The commonest method for removing salt from pans is the "salt leg" (see Fig. 17). This consists of running a bucket elevator into a boot at the bottom of the cone of the evaporator body and lifting the salt into storage bins. Hence, the normal brine level must be 30 ft. or more above the elevator foot, so that a vacuum may be carried. Also, the elevator must be cased at least above the normal brine level so that the vacuum may be broken without emptying the pan. Hence in all but the largest pans there is a long vertical pipe extending down from the lower cone of the pan into the elevator boot. By feeding fresh brine in at the bottom of the "salt leg," instead of the point shown in Fig. 17, the rising current of brine in the salt leg forms an automatic sizing device and prevents crystals settling into the boot till they have attained a certain size. Even without this device, the natural circulation in the pan holds small crystals in suspension, so that a vacuum pan product is always quite uniform.

Buckets for a salt elevator are usually of screen to allow drainage. At that, the discharge from such an elevator will be nearly 50 per cent water. In one case a chain drag conveyor is used, but this results in excessive rusting of the worn iron surfaces at each shutdown. The best design has the elevator chain running in recesses in elevator casing so that dirt from the chains cannot fall into the salt.

A less common method for removing salt from a pan is the use of receivers and centrifugals. The Worcester Salt Co. is so equipped. Below the cone of each effect is a cylindrical receiver with gate valves top and bottom. The top valve is open and the bottom one closed during usual operation, and salt settles into the receiver as

FIG. 17. SALT PAN WITH CONTINUOUS ELEVATOR

formed. A sight glass is provided to show when the receiver is filled. When a charge has accumulated, the top valve is closed, the bottom one opened, and the entire charge dropped into a centrifugal below.

Vacuum pan salt has a very characteristic grain. Since the crystals are suspended in a strongly agitated solution during formation, loose crystal aggregates cannot form, and the salt is in the form of hard, uniform cubical grains (Fig. 16). When rolled between the finger tips, they feel almost like spheres. This hard uniform structure makes a salt which dissolves more slowly than grainer salt. Due to its smaller relative surface and more compact structure, it is not so hygroscopic as the more open grains of grainer salt and hence pan salt makes a more free-running table salt. Also, due to its more regular surface, pan salt does not occlude mother liquor so readily, and hence is usually purer than grainer salt.

FINAL TREATMENT

If a salt leg was used, after draining several days in bins the salt is withdrawn and conveyed to storage piles, from which it is reclaimed to the driers. Where receivers and centrifugals are used, the centrifuged product goes directly to the driers. These are usually about 6 ft. in diameter by 30 ft. long, steam heated, and supplied with a hot air blast. There may be drums or coils to furnish direct heat, and air is usually blown over tempering coils before entering. The Inland-Delray Co. operates a direct coke-fired drier, and claims that it has no difficulty in making a high-grade product. The steam-heated drier is, however, much commoner. The drier shell either is made of maple staves or, if steel, is maple lined.

From the driers the salt is elevated to screens, from which the various sizes go to storage bins and packing machines. The finest size recognized is through about 80 or 90 mesh and is called "paste" or "flour." Above this the grades recognized vary with the plant. Little pan salt is put out finer than 18 or 20 mesh. Some recognize but one size between 20 and 80 mesh, others make several grades in this range. The product obtained between, say, 20 and 80 mesh, carefully dried, and treated with 0.1 to 0.3 per cent of some inert fluffy material such as magnesia, forms the "shaker" or best grade of table salt. Such a product must be packed in paraffined paper cartons to protect it from moisture and to insure "free-running" when it reaches the consumer.

Handling dry salt is very easy compared to handling wet salt. Screw conveyors running in maple troughs, and bucket elevators on rubber belts are successfully used without discoloring the product.

The highest grade salt, when put up for table use, is usually in the familiar 2-lb. pasteboard box. Some of this very fine or "paste" salt is sold for use as loading material in certain products where it is in effect an adulterant. The ordinary grades are shipped in 2-, 5-, 10-, 25-, or 50-lb. cloth sacks, and in the standard 280-lb. barrel. Much is also sold in bulk.

The writer wishes to express his appreciation of the many courtesies offered him by salt manufacturers in the Detroit and Saginaw district. Especial acknowledgement should be made to the Inland-Delray Salt Co. of Detroit, the Worcester Salt Co. of Ecorse, Mich., the Canadian Salt Co. of Windsor, Ont., and the Willcox Engineering Co. of Saginaw, Mich.

Satisfactory Etching Reagents

Below is a list of most of the common reagents in use at the Bureau of Standards for etching various metals and alloys before microscopic examination, with brief remarks as to the suitability of each and the various features which are revealed:

Material	Method of Etching	Remarks
Copper and copper-rich alloys (brass, bronze, aluminum bronze).	An ammoniacal or an acid oxidizing solution.	Suitable oxidizers for use: hydrogen peroxide, ammonium persulphate, potassium permanganate, potassium dichromate, chromic acid, ferric chloride.
	Ammoniacal solution of copper ammonium chloride.	Electrolytic in its nature.
	Oxidizing acids.	Nitric acid and chromic acid.
	Aqueous solution of silver nitrate.	The film of precipitated silver must be removed.
	Concentrated ammonium hydroxide.	Accompanying oxidation is necessary to produce satisfactory results.
	Heat tinting.	Valuable for certain bronzes.
Aluminum and aluminum-rich alloys.	Hydrofluoric acid	An approximately 10 per cent aqueous solution is used, a supplementary immersion in concentrated nitric acid or in chromic acid may be necessary to clean the surface.
	Aqueous solution of sodium or potassium hydroxide.	0.1 per cent aqueous solution is suitable for revealing the constituents, more concentrated solutions for grain boundaries.
Lead.	Nitric acid.	
Lead and tin alloys, including "white metals."	Dilute nitric acid.	Alone or with an addition of chromic acid.
	Dilute hydrochloric acid.	
	Aqueous solution of silver nitrate.	
Nickel.	Concentrated nitric acid.	Used alone or in a solution of glacial acetic acid, approximately nitric acid 50, acetic acid 40, water 10 per cent.
	Electrolytic etching.	
Nickel-rich alloys. (Monel metal, Benedict nickel, nickel brass, invar, etc.)	Same as for nickel.	Same as for nickel.
	Ferric chloride.	
	Ammonium persulphate.	
Zinc and zinc-rich alloys.	Sodium hydroxide; mixture of chromic and nitric acid.	Alcohol solutions, approximately 1 per cent.
	Iodine.	
	Electrolytic etching.	
Gold, platinum and "noble" metals and alloys.	Aqua regia.	
Silver and its alloys with copper.	Nitric acid.	
	Ammonium persulphate solutions.	
Wrought iron, "pure" iron.	Nitric acid.	2 per cent alcoholic solution, commonly used.
	Picric acid.	
	Cupric reagent (Stead's reagent)	To reveal phosphorus banding, and similar structural features.
Carbon steels.	Nitric acid, picric acid and cupric reagent, as above.	Used to color cementite.
	Hot alkaline sodium picrate.	
	Hydrochloric acid.	
Alloy steels.	Same reagents as for carbon steels above.	For revealing grain boundaries.
	8 per cent alcoholic picric acid, very prolonged etching.	
	Sodium picrate.	
Cast iron.	Picric acid, or nitric acid as above.	For steels showing free carbide.
	Heat tinting.	
	Sodium picrate.	
		To identify iron phosphide and manganese sulphide.

Recovery of Diamond Powder From Waste Paste

BY RICHARD G. BERGER

DIAMOND powder, commonly called "diamond dust," suspended in olive or lubricating oil is much used as an abrasive for cutting facets on diamonds, shaping sapphire and diamond points, and polishing where a very hard abrasive is required and where nothing else will serve satisfactorily. After a period of use on the iron polishing wheel or bronze cutting wheel the diamond powder becomes clogged with metal, dirt and carbonaceous matter which covers the sharp crystal diamond powder so that it no longer acts as an abrasive.

In the past it has been customary to throw away waste diamond powder paste, but by use of the following procedure the diamond powder present in the accumulated waste can be recovered and used repeatedly. Whether the recovery of the diamond powder is a paying proposition or not depends upon the amount present in the waste. The waste paste taken from the bronze cutting wheels, called "sawing machinery" in diamond cutting establishments, is much richer in diamond powder than that from the iron polishing wheels which have been used for cutting facets on diamond gems.

IS THE CRYSTALLINE DIAMOND POWDER CONVERTED INTO GRAPHITE DURING POLISHING?

The small yield of diamond powder and the large yield of amorphous carbon (graphite) obtained in the recovery from waste paste taken from polishing wheels has led to the question in the writer's mind if there may not be a possibility of the crystalline diamond powder being converted into graphite during the operation of polishing facets. Under somewhat different conditions R. Vogel and G. Tammann (*Inst. Phys. Chem. Göttingen, Z. physik. Chem.*, vol. 69, pp. 598-602), found that when diamond chips were heated in a quartz tube at 1,000 deg. C. and at higher temperatures at times a partial and even complete conversion into graphite took place. It does not seem improbable to the writer that on the polishing wheels with the combined elevated local temperature and great pressure at the point of contact between facet of gem and diamond powder conversion of the crystalline diamond powder into graphite may take place.

Under no conditions should the dry diamond powder or paste be heated over a free flame, for although a diamond of gem size will not burn in an ordinary flame, the experience of the writer has been that diamond powder of fine mesh such as is used for abrasive purposes behaves differently and readily burns to ash in a free flame.

SOLVENT TO BE USED

The solvent to be used for extraction depends upon the kind of oil which has been used as a carrier for the diamond dust. Dry acetic ether (ethyl acetate) is the best solvent available with petroleum pastes. For the removal of sand and glass particles fusion with sodium hydroxide has been found to be much more rapid and satisfactory than treatment with hydrofluoric acid, as where there was considerable sand, such as in floor sweepings, sand particles were found to be present even after four treatments with hydrofluoric acid.

The procedure as given can be used also for recovery from waste rags with which machinery has been wiped

off and for sweepings from work benches. The waste rags should be washed in acetic ether or benzene, and the solution containing the powder evaporated down to dryness, and the solid residue put through the regular procedure.

METHOD OF REFINING WASTE

Extract the oil present in the waste by shaking thoroughly the waste paste with acetic ether or benzene, and allow to settle, decanting the clear supernatant solution after the paste has settled, which will take anywhere from ten minutes to three hours. Repeat several times until the deposit is free of oil, which state can be seen when the solid particles settle readily. The oil must be completely removed, as even small amounts will cause considerable annoyance because of the disagreeable odors generated during the acid treatments and difficulties in filtering the residue. If desired, the solvent used for extraction of the oil can be recovered by distillation.

Dry the paste which has been freed from oil on a steam table or in a hot air bath at a temperature not exceeding 130 deg. C. until it is free from solvent, and treat in an evaporating dish under a chemical hood with strong nitric acid. Heat over a free flame, adding nitric acid until there is no further action, but do not allow to go to dryness. Dilute with water, allow residue to settle, and decant the supernatant liquid. Repeat the washings and decantations until the deposit is clean. Dry the residue on a steam table or in a hot air bath at a temperature below 130 deg. C.

Heat the dried powder in an evaporating dish with strong hydrochloric acid under a hood until no further action, but do not carry down to dryness. Dilute with water, allow residue to settle and decant the supernatant liquid. Repeat the dilution and decantation until the solid deposit is clean. Put in an evaporating dish and place on a steam table or in a hot air bath below 130 deg. C. until dry.

Melt solid sodium hydroxide in a wrought iron crucible. Remove the flame and allow to cool from red heat to dark and while the mass is still molten add the dried residue, stirring with a platinum wire or iron rod. Place a cover on the crucible and heat gradually to dull red heat. Cool until the sodium hydroxide is solid and then leach out the crucible by placing it in water and heating until all the sodium hydroxide is dissolved. Wash the solid particles in an evaporating dish or in a beaker by repeated decantation with water until clean. Dry the deposit, which should be clean, bright and crystalline diamond powder.

If there should be considerable black particles of amorphous carbon (graphite) present, these can be removed by adding the dried powder to a solution of specific gravity approximately 3.2, allowing the crystalline diamond particles to settle and pouring off the suspension of carbon particles.

Bridgeport, Conn.

Canada's Wood Pulp Supply Reaches Enormous Total

An official estimate of Canada's pulpwood resources places the supply of all woods suitable for pulping in the Province of Quebec at 360,000,000 cords; 150,000,000 cords are of spruce and balsam. In Ontario there are 250,000,000 cords and in New Brunswick 36,000,000 cords of spruce and balsam. The present annual rate of cutting of these two species is 5,750,000 cords.

Finish of Metallic Materials

Heat-Treatment Yields Quality, Finish Gives Durability and Appearance—Finish of Metallic Materials Discussed as an Essential Detail in Modern Manufacturing, With Brief Notes on Cleaning, Polishing, Lacquering, Coatings, Slushes and Wrapping

By SIDNEY CORNELL

MODERN methods of manufacture demand specialization, but in the routine many important details practiced in an industry have been somewhat neglected. Thus, although we may have a factory specializing on cutlery, on sheet metal goods, on cans, on this, that and the other thing, fundamental processes occur in all of them, which if studied in detail would yield greater returns than at present. There are few if any specialized concerns practicing heat-treatment only, or polishing and finishing only, yet these two items largely determine the worth of vended articles. Methods used are often employed in a manner not up to the standard represented by the position the concern holds in its line and loss of economic value results.

Articles are commonly finished to give a pleasing and salable appearance; and more important considerations of protection against rust, corrosion or wear are of a secondary nature from this viewpoint. Many concerns in the past few years have attacked problems they did not thoroughly consider, due to lack of knowledge of these highly important details of their business. Or, on the other hand, changes in the finished product were brought about by war-time changes in their materials. For instance, lacquered products are not the same as they were. Polishing as practiced in this country is not quite up to foreign standards, especially French, and the American mechanic does not seem to be able to file metal with the skill of a Frenchman.

In the writer's opinion, finishing the metal should be regarded from a different angle, so that manufacturers should understand that a protection against corrosion in the form of a proper finish should primarily be aimed at, and this finish at the same time should furnish a pleasing and salable article.

It is with a hope of noting the various necessary factors that this article is written, and it is further hoped that others will contribute much of importance to this art. Its position in the scheme of modern production is as important as is heat-treatment.

FIVE DIVISIONS OF THE SUBJECT

The subject naturally divides up into five steps, some or all of which are practiced on all articles sold. They are:

1. Cleaning after fabrication.
2. Polishing, buffing, burnishing, sand blasting or rougher finish depending on the nature of the article.
3. Coloring of polished articles, by numerous methods producing an oxidized film, a subject whose discussion is deferred. Painting rougher articles. Japanning of pressed metal goods or articles of a similar nature. Lacquering.
4. Coating finished articles with a protective metal or other semi-metallic coating. Calorizing, galvanizing and electroplating of metals.
5. Slushing oils, and other temporary coatings.

It is commonly believed that cleaning is a simple operation, whereas such is far from being the case. Many troubles arise over lack of understanding what cleaning really is. Cleaning primarily has to deal with the removal of "dirt." Chemically it would be hard to define "dirt," which may mean a very complex foreign substance, varying from pure silica (sand) up through innumerable chemical compounds into very complex animal, vegetable and mineral matters. Detergents, soaps and cleaning compounds are more or less simple substances which will act on "dirt" of varied chemical composition and physical nature in different ways. Thus all cleaning compounds may be said to have a "factor of adaptability," many of the common detergents being of very limited use in cutting factory dirt.

ACTION OF CLEANERS

A glass surface is not exactly smooth, but consists of a series of very flat undulations. When such a surface has a coating of grease or oil these small hillocks act as banks for the formation of small drifts of dirt. In rougher metal parts, no matter how highly polished, these inequalities in smoothness cause greater drifts, and in fabrics these accumulations may become relatively enormous. Dirt and its cementing oil will vary widely in composition dependent on local conditions, and there can be a wide variation in the nature and composition of the oil or grease coating the solid particles. Their release is not so simple as it might seem, for although certain cleaning agents will dissolve some oily binders they may not clean a certain article at all, since there is no universal solvent for all oils.

While the theory of soaps is still debatable, they may act by forming water-soluble compounds, emulsifying the materials to be removed, or by forming absorption bodies with other substances. In the latter case removal is largely a mechanical operation. In some one or more of these methods the dirt is loosened and then whisked away by means of a stream of flowing water, brushing by a broom, wiping by cloths, fibers, etc. Various cleaning materials commonly used may be listed, many of which are not necessarily desirable, or used to good advantage in particular places.

1. Gasoline, kerosene, benzine, benzene, solvent naphtha, carbon bisulphide, carbon tetrachloride. All of these liquids are volatile, expensive, some dangerous, and none a perfect dirt remover.

2. More common chemicals form a second group, embracing soda ash, sal soda, sodium hydrate lye, potash lye or lime water. Common yellow laundry soaps, sulphuric acid, usually diluted to 10 per cent, hydrochloric acid, nitric acid and hydrofluoric acid. Two rather dangerous cleaners are left to the last of this group—potassium cyanide and oxalic acid. Ammonium carbonate might be included. Substances in group 2 are seldom intelligently used; for instance sal soda, con-

taining a large amount of water of crystallization, is often used, when soda ash would give like results at a lower cost. Other examples are the careless use of cyanide and oxalic acid.

3. Various patented and often secret combinations of the above materials with other cleaning chemicals. A majority of these compounds are frauds, but there are several reliable concerns turning out cleaning mixtures which are excellent and do the work. As a practical consideration, economic and otherwise, it is advisable to deal with a reputable vender of this material, since it is quite impracticable for a small concern to make a cleaning compound good for all its work, and in view of the normal variation in raw materials, impossible to obtain a uniform mixture without accurate chemical control.

4. Some material of group 3, when used in conjunction with electrolytic cleaning, probably represents the most advanced step in the art of cleaning. In an electrolytic bath composed of a solution of some good cleaning compound, the detergent acts on some of the dirt in various ways as pointed out above. Electrolysis reduces some oxides to metal. A third mechanical action takes place by evolution of gas on the surface of the article being cleaned, which action lifts off slivers of dirt. Temperatures used in such solutions are various, some being used at 150 deg. F., others up to the boiling point. The tank is provided with a close steam coil for this purpose. The electric current used may run to 110 volts or a low tension, 10-volt current may be used. In degreasing wools it is common to reduce the amperage after the process has progressed—e.g., 65 amp. at the start and 20 amp. at the finish. Many cleaning compounds offered for such use contain potassium-sodium cyanide, and caution is suggested, as poisonous cyanogen gas may be liberated under electrolysis.

POLISHING

In a discussion of this sort it would be quite impossible to cover the subject of polishing completely. To be finished, many articles must be cleaned, polished, cleaned again to remove polishing materials, and lastly coated in some manner.

After polishing, all materials must be further cleaned to rid them of tallow and grease, and in many classes of work real difficulty is experienced in the removal of crocus, tripoli and rouge, even with the use of satisfactory cleaners. Work must be clean before it can be finished.

Polishing, like other trades, had its tricks, but most of the polishing supplies are now supplied by reliable concerns, superior to the hand-made canvas or emery wheels, buffs and burnishers formerly made by the artisan, who seems now to have almost disappeared. The simplest finishing wheel is the scratch brush, used in carding, an operation discussed¹ under "Bluing and Browning." Whip brushes of wire are used to produce the so-called "satin finish," while a brush with wires set closer together produces a matte effect. Swing brushes are used to produce a frosted effect on soft metals, and contain only four (seldom six) spokes topped with small wire whisks. In order to obtain a finish with wire wheels such as given by sand blasting it is often necessary to sharpen the wires by holding a block of emery against the brush turning in the wrong direction. Wire brushes are made from various kinds of metal wire. When carding brass, a wheel of brass wire must be used, as steel wire discolors the work. Similar precautions are

necessary for brushing copper and other metals. Stiff wire wheel brushes are often used to clean castings prior to plating.

Excessive pressure is not necessary for this operation and it only wears out the wires. It is the cutting action of the wire ends that cleans, not the rubbing with the sides of the bristles. Wet grinders are operated at approximately two-thirds the speed of dry grinders, polishing wheels one and one-half times as fast and buffing wheels at twice the speed of dry grinders.

Canvas wheels are made from layers of heavy canvas cemented together, yielding a resilient surface, largely used for rough polishing, or "roughing out." Leather wheels are used for oiling and finishing. Semi-flexible but hard leather wheels coated with emery are used for general work. Soft wheels should be used on silver, nickel or brass; medium hard wheels on saddlery, piano- and automobile-hardware, and for stove and agricultural implement parts; while a hard wheel should be used for heavy brass, gold, and for oiling almost any work. (A wheel with polished face should generally be used for oiling finished work.) For especially fine polishing, sheepskin wheels may be used, and for some classes of work felt wheels find favor.

Aside from wheels, the following polishing materials will be mentioned, glue and emery being neglected, although their importance is evident. Turkish emery is the standard, with Greek and American following in favor. Tripoli, a light-colored infusorial earth, is compounded with various greases and waxes so that it will adhere to a polishing wheel. Care should be taken in this selection, as the mixture may yield a cutting compound in place of the polishing compound required. Other grinding aids which may be mentioned are silex, pumice stone, crocus (iron oxide), hydrated lime, precipitated chalk, rotten stone, etc.

TUMBLING BARRELS

The next simplest polishing mechanism is the tumbling barrel. The simplicity of the tumbling operation is such and the work done so good that it is a wonder that more use is not made of this mechanism. Small duplicate work is usually treated in this device, but articles with finished, square, sharp corners cannot be tumbled. Barrels are operated both wet and dry. The packing materials are leather meal, sawdust, sized flint, etc., for dry tumbling, and solutions of cleaning compounds in wet tumbling. In wet tumbling, steel balls are often used, but the size of the ball must be chosen with great care. If there is the least doubt as to whether a cleaning compound in use in a tumbling barrel is inadequate or that a cleaner used on some other job might be substituted, it would be well to try a solution of borax soap, Ivory soap, or some non-alkaline compound.

Barrels are made in a variety of shapes, but in all types the speed of rotating must be slow enough (ordinarily 40 r.p.m.) to permit the work to roll on the ascending side of the barrel and not be held stationary against the lining by centrifugal force.

Burnishing with small steel balls contained in a tumbling barrel will produce work comparable to buffing. Figured work is well done, but the ball used must be of such size as to slide readily in and out of the crevices, angles, curves and depressions. Such burnishing gives certain alloy parts a luster that cannot be duplicated by any other means, and in a general way it may be said that the smaller the ball the better the result.

¹To be published in a subsequent issue.

Enough balls must be provided, usually running twice as many balls by volume as the work, with a hot 2 per cent solution of borax soap equal in volume to the volume of the work. This burnishing may also be done after plating and is probably as economical in direct labor as any existing process for finish.

SANDBLASTING

Many articles, especially tools, are given dull matte finish by sandblasting. Parts of rifles and other small arms are sandblasted as a cleaning operation, and British bayonet blades were sandblasted for finish. The small articles can be sandblasted semi-automatically in barrels or on revolving tables. Work on revolving tables must be turned over after each passage under the nozzle in order to be finished on all sides.

PICKLING

Less finely made metallic articles of commerce may be covered with the well-known blue-black scale if it was heated during the process of formation. Before such an article can be successfully coated with a material other than paint, this scale must be removed and this is usually done by a process called pickling. "Pickling" ordinarily means immersion in sulphuric acid. Sulphuric acid of fairly high concentration will not entirely dissolve such scale, and the reactions taking place in the usual pickling tank are exclusively a direct solution of iron oxides. Scale is actually removed partly by dissolving the iron underneath the scale, and partly by forcing it off the metal by hydrogen gas generated between the scale and the surface of clean metal beneath.

Acid pickling is fundamentally an incorrect operation, as a loss of good metal takes place. Tests determining the iron lost in pickling sheets before galvanizing showed an average of 2.32 per cent less by weight. It might be stated here that titanium-treated iron is reported as losing only half this amount in pickling, but why titanium in the amounts present should make steel acid-resistant is not apparent, as the mechanical process of scale removal seems to depend upon the loss of some good metal to generate hydrogen to lift off the scale.

Pickling acids are sulphuric, hydrochloric and hydrofluoric. Sulphuric acid, as mentioned, is the common pickling agent. Mixtures of sulphuric and hydrochloric acids do not quicken the process, but quite the reverse, retarding the action materially. Impurities such as arsenic or lead retard the action of sulphuric acid materially, often cutting down its effectiveness one-half. Sulphuric acid pickle ranges in strength from 3 to 8 per cent, and is kept as near boiling as possible. Lead-lined tanks and lead pipe are necessary; discharging live steam directly into the solution is often practiced for heating. Agitation of the articles being pickled increases the output of correctly cleaned articles and cuts down the time of immersion. On some small articles from six to ten minutes is required, using 6 to 8 per cent pickle. With a weak solution of say 3 per cent at lower temperature (approximating 175 deg. F.), the time of immersion required to remove the scale will be thirty minutes or more.

The amount of acid required will vary with the nature of the articles being pickled. On fair-sized work about 200 lb. of 66 deg. sulphuric acid will be required per ton of material pickled, while on heavy material such as sheets the work can be done for as low as 125 lb. per ton of sheet.

Thorough washing in clean water is necessary after

pickling, and often "liming" is done to neutralize any remaining acid. Small springs pickled to remove defective browning developed "acid" brittleness to a marked degree; this was corrected by heating the pieces for approximately one hour at 400 deg. F., just under the usual drawing temperature.

ELECTROLYTIC PICKLING

The loss of metal in acid pickling is an important matter, and as indicated approximates 2 per cent. Removal of defective blue or brown coloring on gun parts may be readily accomplished in an ordinary electrolytic cleaner, the oxide being reduced to metal. Parts so treated did not change in dimension, some of which were to limits of 0.0001 in. It would therefore seem that the electrochemical process of pickling might be given serious consideration and investigation as to whether it could not replace much of the more wasteful acid pickling. Incidentally, gun springs so treated did not lose their physical properties, and passed inspection perfectly when refinished by bluing or browning.

LACQUERING

An article left in the polished state, except gold or other noble metal, must be protected if it is to stay bright. The simplest protection is lacquer.

There are many lacquers on the market, but none of them is an absolutely perfect coating. A few months at the most will witness the darkening or peeling of such coatings. The best of lacquer can be ruined if applied carelessly, a fact well recognized on all sides. Grades and types of lacquers are almost as numerous as paints, so mention of the process only is made.

Dust and moisture must positively be excluded from a lacquer room. Ventilation is also of high importance. As the solvents are highly volatile and flammable, open flame for lighting or heating must be avoided. Drying cabinets should be maintained at 100 deg. F. properly steam-heated to give such a temperature, controlled by adequate and correct thermometers. Note was recently taken of a temperature reading as 100 deg., whereas the actual temperature was 140 deg., and the manufacturer wanted to know what was wrong with his lacquer! The same conditions have been noted on japanning ovens, operated at a higher temperature.

Spraying probably gives the more even protective coating, and avoids brush marks. Automatic dipping machines have advantages from an economical and production standpoint over the spraying method. Such machines take the work in racks at one end and deliver the lacquered and dried articles at the other end of the apparatus.

Progress remains to be made in getting some method of stripping defective lacquer from work, as lye solutions are not satisfactory; amylacetate is expensive, and recovery systems are not common.

Dip lacquers require the work to be absolutely clean and dry. If moisture or grease happens to be present, the lacquered articles will appear white and cloudy either in spots or all over. Lacquer and work should be at the same temperature. As might be imagined, lacquers are obtainable in all colors, from purely transparent through the varied shades and degrees of transparency, to jet blacks resembling japan finish.

JAPANNING

Briefly, japanning is coating with a black varnish, which is hardened by baking in an oven. It is an inter-

mediate step between painting and porcelain enameling. The solvent in the japan allows it to cover the article completely. By baking, the viscous residue from the evaporation of the solvent is oxidized into an elastic coating, a reaction accelerated by elevated temperatures. Modern japans are baked in from thirty minutes to one hour, and it might be stated that experimentation has developed japans that bake in as short a time as ten minutes. Temperature control is highly important and is often not given proper attention. In other cases the most extreme care and highest type of automatic electric ovens have been installed. Ventilation naturally is important in a japanning department, as it is necessary for safety against fire as well as for proper operation of the process. About 1,200 cu.ft. of free air should be figured upon for ventilation of each gallon of japan baked in an oven. Temperatures as high as 450 deg. F. may be used for baking, and automatic conveyor-type ovens may be used to increase production.

Colored japans require an absolutely even temperature, and an oven which does not lose temperature rapidly or excessively when charged or drawn must be selected. Japans give the high gloss finish to adding machines and automobile parts, the dull black of the telephone, through all ranges of color effects to imitation mahogany, oak or walnut found on steel furniture.

PAINT AND "DOPE"

In a summary such as this a detailed discussion of "paint" would obviously be impossible, but opportunity will be taken to mention new paint which is the result of war work on airplanes. Waterproofing coatings for the fabrics on aircraft wings must dry in a few minutes after application. It was found that when cellulose acetate or nitrate is dissolved in a mixed solvent, such as methylacetate, benzene, acetone and alcohol, and to which is added about 5 per cent of castor oil, there results a quick-drying paint, consisting of an elastic film, with a hard surface. As substitutes for shellac and paint the use of such "dope" is obvious, as it yields a moisture-proof, flexible film. Such coatings will not last as long as paint, but for many purposes they will find extensive application and usefulness.

OILING, SLUSHING AND WRAPPING

There is today a marked tendency toward carelessness in packing salable articles. Bottles seem to be the exception, probably due to their friable nature and the introduction of corrugated paper as a protection medium, and the use of folding boxes as containers. Finished metallic articles should be wrapped in tissue paper, or if of a nature requiring it in oiled paper or in heavy manila.

Polished and highly finished tools, metal parts, etc., should be given a proper coating of oil. Any oil will not do, and there is a large loss annually in defective goods due to the use of a common machine or engine oil as a slushing agent. The old practice of coating bearings and shafting of machines with white lead is a messy procedure at the best, especially for the person who has to remove it. Still there are a number of excellent semi-fluid slushing oils on the market, varying in consistency and in color from colorless to green. They successfully keep out moisture and air, yet are readily removed when desired.

These substances should be applied hot, either by dipping the article into a body of melted oil or by painting with hot oil. On cooling these oils set to a stiff,

jelly-like mass, are free from acid and corrosive materials and do not decompose.

Other coatings containing wool grease, which on oxidizing glues itself to the surface of the article, are not as desirable as more modern types, although they are a very good substitute for white lead.

A satisfactory slushing oil to resist corrosion can be made by mixing 55 per cent kerosene by weight with 45 per cent English wool grease. Another less satisfactory protective coating may be made from 50 gal. of heavy-bodied machine oil, to which there is added 900 lb. of red petrolatum. This will yield about 1,250 lb. of coating grease, which should be either applied by hot dipping or cold painting. There is a tendency to use too much slushing compound in many cases, and hot dipping with a proper draining is recommended for economy.

CONCLUSION

Many of the subjects mentioned above are worthy of more detailed attention, and it is certain that many persons have acquired valuable experience when using some of them. It is suggested that such men contribute such information to the technical press, as there seems to be a dearth of such matter in print. The writer further believes that many manufacturers will gain much by paying more attention to apparently insignificant details of operations in their polishing room, electroplating room, lacquer room, or wherever their finishing may be done, as there is possibility for big savings and improvements therein.

Yields of Alcohol From Wood Waste*

Softwood lumber mill waste can be made to yield 20 gal. or more of 95 per cent alcohol per ton and hardwood waste about half as much. Some actual yields obtained from the waste of various woods are given in the following table:

Kind of Wood	Softwood Waste		Gal. of 95% Alcohol From 1 Ton of Wood
	Percentage of Wood Convertible Into Sugars	Percentage of Sugars Fermentable	
White spruce.....	23	71	25.8
Longleaf pine.....	23	72	25.1
Red spruce.....	22	72	24.0
Norway pine.....	25	66	23.4
Idaho white pine....	21	74	23.4
Western hemlock....	21	77	23.0
Montana white pine..	20	75	22.0
Lodgepole pine.....	21	67	21.8
Sugar pine.....	20	66	21.5
Douglas fir.....	21	67	20.7
Kind of Wood	Hardwood Waste		Gal. of 95% Alcohol From 1 Ton of Wood
	Percentage of Wood Convertible Into Sugars	Percentage of Sugars Fermentable	
Silver maple.....	20	47	14.1
Birch.....	20	46	12.9
White oak.....	17	50	12.4
Red gum.....	20	38	11.0
Sycamore.....	18	38	9.7
Hard maple.....	18	34	9.1
Red oak.....	19	30	8.1
Cottonwood.....	18	30	7.2
Slippery elm.....	16	26	6.0

The manufacture of industrial alcohol is at present about the only feasible method of utilizing lumber mill refuse on a large scale. An alcohol plant with a daily supply of 180 tons of wood can produce 3,600 gal. of alcohol at a cost, under present conditions, of approximately 25c. a gal. The success of plants now in operation justifies a serious consideration of this process by mills having a large quantity of waste.

Easy Money From Peat

Wonderful Invention for Extracting Methyl Alcohol and Gasoline Out of Peat and Money Out of the Pockets of Investors — Description of the Apparatus and of the Supertechnical Process Used, Which the Inventor Says Will Put Standard Oil Out of Business

WE COUNT among our pleasant acquaintances a gentleman who retains the Yankee tradition of wanting to know; holding in maturity that engaging quality of curiosity which most of us enjoy as children but which, to our great hurt, we are likely to slough off in some inexplicable manner before our student days are over. Our only regret in regard to what follows is that owing to a quality of intense shyness he withholds permission to mention names and places. We may say this much but no more, so we hasten to acquaint our readers with a record of his experience in "looking up an investment." Our comments may be a trifle fanciful, but there is no imagination in his statements of what he saw and what he heard. They were carefully recorded while his memory was fresh.

WONDERFUL OPPORTUNITY FOR INVESTMENT

He learned of a wonderful opportunity for investment; an opportunity to make the original purchasers of telephone stock turn in their graves with envy; a chance to participate in a corporation for the development of a chemical process that will (or perhaps in the interest of sound conservatism we had better modify the tense and say that *should*) make the Standard Oil Co. look like thirty cents. The great invention, he was told, consists in making 20 to 25 gal. of pure methyl alcohol and 120 to 125 gal. of high-grade gasoline out of a ton of peat—out of a ton of any old kind of peat. He availed himself of the opportunity to meet the inventor and his assistants Charlie and George, together with upward of a dozen other gentlemen who were, partly already—partly pledged and partly prospective—investors. Most of them were actually men of means. He witnessed an official test of the process, and he saw the apparatus in operation.

On arriving at the place indicated, which is the site of the initial plant, he found the inventor installed in his office in a house, with a desk covered with papers, with bottles containing different colored liquids, and with numbers and cryptic labels that are not designed to be understood by the common, everyday chemist. The inventor was a very affable gentleman, well along in years, but showing no trace whatever of the infirmities of age. Our friend learned that the official test was to take place at 10:30 a.m., which was shortly after his arrival, and that the option to buy the stock held by a major portion of those present was to expire at noon.

CAPITALISTS CRY FOR IT

"I might as well tell you, gentlemen," said the inventor, "that last night a group of New York capitalists came out with their chemist, and after an unofficial test which was carefully passed upon they were so taken with this process that they offered me \$4,000,000 for 40 per cent of the stock! I couldn't accept because I am

resolved to retain 60 per cent myself, and I felt in honor bound to have a talk with you beforehand."

At this point one of the investors interrupted him with, "You shouldn't sell a share, Professor! We are able to provide all the funds you need."

STANDARD OIL NEED NOT APPLY

"Well," the Professor, as they called him, went on, "early this morning there was a group of California oil men out here; they drove out in automobiles; and they were so gratified by what they saw that they offered to pay me \$500,000 in cash for the rights in California, and somewhat less for similar rights in each of the two other Coast states, Oregon and Washington. It looked tempting, because we could pay 40 to 50 per cent dividends on our stock from this offer without making a gallon of gasoline. One thing that held me back was that I can't make out whether they were Standard Oil men or not. I don't propose to let John D. Rockefeller or any of his associates buy one share of this stock. Why, two weeks after we begin to produce we shall have the whole Standard Oil crowd on their knees before us! I told those fellows I'd think it over till 6 o'clock this evening. I figure, though, that the rights are worth a good deal more than they offer. We can put up plants in nearly every major town in every state. They'd be getting their rights very cheap at those figures.

"Another thing I have to say is that our plant is progressing better and faster than I expected. The men have been very faithful. I am 50 per cent ahead on costs and 50 per cent ahead on construction. We can begin to turn out gasoline on Jan. 15.

EIGHT-CENT PRICE IS PROFITEERING

"Now we can start out selling the gasoline for 20c. a gal. Of course we could sell for a good deal less. My agreement with you gentlemen who have subscribed is not to sell it below 10c. a gallon, although we could sell it for 8c. and still be profiteering. But there's no use in selling too much below the Standard folks. That would only mean a fight, and I don't see the use of it. Their gasoline has been costing them 14.8c. a gal. That is inside information, and I *know*. We shall be able to sell all we make all right."

"Professor," said Charlie, one of the assistants, "Did you tell the gentlemen about our success yesterday?"

"Why, no," said the Professor. "I forgot all about it. There's an automobile dealer near by who wants to contract for half the entire output of our plant, and to pay for it in advance at 20c. a gal. There are a number of others also who are after it. We shall have no trouble in making sales.

"I'm almost getting ready to begin building a second plant. It's just a little matter of a real estate deal that's holding me back."

"But, Professor," said one of the investors, "wouldn't it be better to start the one, and then build up extensions from the profits on the first?"

"No, sir!" he replied. "I'm getting old, and I want to put this thing through. I've got no time to dally. We must have four plants in operation by July 1!"

George (the other assistant) asked if he hadn't better go and get "that pressure tubing." It seems the evening before they had burst a piece, and George was urged to get into a motor and hurry back with the new one. Then Charlie said he thought all the gentlemen who were coming were there, and he suggested that they might as well start the official test. The Professor agreed to begin as soon as George returned; which he did shortly, with about 3 ft. of rubber hose.

COMPONENTS OF THE MYSTIC APPARATUS

He then led the way into a large cellar under his house, where, on an improvised table about 16 ft. long and 2 ft. wide, the mystic apparatus was set up. Unfor-

tunately we lack working drawings, but our friend made a sketch from memory, and we are able to give a description that is approximately correct. The series consisted of:

1. A bicycle air pump.
2. The air cooler or purifier.
3. The combustion chamber.
4. The alcohol converter and catalysis chamber.
5. Condenser and alcohol receiver.
6. The pressure regulator.
7. The gasoline converter, catalysis chamber and liquefier.
8. Gasoline trap.
9. Gasoline receiver.
10. An automobile tire pump containing a remarkable valve invented by the Professor, connected with the alcohol converter and the gasoline converter.

The Professor told the boys to fill up the condenser with water and then George took his place at the bicycle pump while Charlie manned the automobile tire pump that contained the remarkable valve.

He then explained how George pumped ordinary air into the system, and that the cooler, or purifier (which consisted of a coil of pipe, air cooled), cooled and purified the air before it entered the combustion chamber. This (the combustion chamber) was a cylindrical apparatus provided with a grate underneath, and with an unused feeder above. The Professor took a few handfuls of moss, which was the peat, opened a door of the combustion chamber, put in his peat and then sealed the door shut. He lighted a bunsen burner, put it under the grate below the peat in the combustion chamber, and said,

"Now begin, boys!" Tense excitement reigned while the Professor began gesticulating, like the walking-beam of a steamboat; one hand up and the other down, then 'tother hand up and the first one down, first very slowly, and then speeding up slightly until they had good, synchronized action.

NOT ONE BIT OF HEAT WASTED

One of the guests placed his hand in the combustion chamber and remarked that it was cold, although the operation was already in process. The Professor cautioned all present to keep their hands off the apparatus, as it was very delicate, and then he explained to the inquirer that this was a peculiar feature of his invention. "The combustion," said he, "is going on all the time, but not one bit of heat is wasted. We use it all."

"Now that peat," he continued, "is all being burned to CO₂ except the ash," which seemed to our friend to be doing pretty well for the cold combustion of peat. "The CO₂," he explained, "is carried over into the alcohol converter, where a high vacuum is maintained, and there in the presence of a catalyst" (which he had discovered) "part of the CO₂ is converted into methyl alcohol."

In other words, we have at this point, which the Professor did not take the time to explain, the highly original reaction:

We don't want to steal any of the Professor's secrets, but we merely suggest that, in addition to his catalyst

in the converter he may have an argon burner in the combustion chamber! The Professor didn't say so, but why shouldn't he have one? After this methyl alcohol reaction we are ready to believe almost anything. It might worry Irving Langmuir, but if he could invent an argon-filled lamp why shouldn't the Professor invent an argon burner? However, things proceeded to happen so fast that we have no time to pause for a reply.

From the converter the unconverted CO₂ passes into a pressure regulator, of which only the outside was visible, and, according to the inventor, thence into the gasoline converter, which is a second catalysis chamber with a complex arrangement of baffles (which were not exhibited), and containing another catalyst which was discovered only after experimentation with "400 metals." This converter is operated under 300 lb. pressure, the Professor announced, and, to prove it, there was a pressure gage that registered 300 lb.

This variety of pressure, the "high vacuum" followed by 300 lb. to the sq.in. in the series of apparatus, was accomplished by means of Charlie working at the automobile tire pump which contains the Professor's remarkable valve. By this Charlie produced the high vacuum in the alcohol converter by the up-stroke, and the 300 lb. pressure in the gasoline converter by the down-stroke.

That valve alone was worth going a long distance to see. Unfortunately it was so inclosed that our friend could not see it.

From the converter, which is also a liquefier, the gasoline passes out into a trap and thence into a gasoline receiver. That is the operation. In no more time than it has taken to tell it the Professor exclaimed, "The operation takes eight minutes, gentlemen, and" (looking at his watch) "seven minutes are gone—seven minutes anna half. Slow down, boys!" And the walking-beam motion began again with the Professor's elbows, while he looked diligently at his watch. "Slow-er. Seven an' three quarters. E-i-g-h-t minutes. Stop! Gentlemen, the operation is completed."

He opened the smaller alcohol receiver, and there it was, over half full of pure water-white methyl alcohol, "absolutely pure excepting only for a little water in it," he said. The gasoline receiver was better still and showed a larger quantity. It also seemed to have more speed than the alcohol receiver because it leaked gasoline even before the pumps were started. "That," said the Professor, "is pure hexane, C_6H_{14} , 71 deg. pure. The gasoline you buy is only 57, but this is 71 deg."

GASOLINE "71 DEGREES PURE"

Somebody wanted to know what he meant by degrees pure. The Professor asked him if he was a chemist, and on getting a negative answer, he said, "It is rather hard to explain if you don't understand chemistry, but there are degrees of purity, and this is 71 against ordinary gasoline, which is only 57." Some people are never satisfied. It made the Professor a little testy, for he said:

"My gasoline is 71 deg. pure, and if you can get any in New York that is as pure as I am making here I'll give you my 60 per cent of stock in the company. At Eimer & Amend's you can get small bottles of very pure gasoline, but it isn't as pure as this."

We merely want to call attention to more wonders of catalysis in this invention, and to ask Prof. Bancroft, for instance, who has spent years in research on the subject, what he has to say, or to call on Sir Ernest Rutherford to explain how he feels after his few atoms of hydrogen derived from an atmosphere of nitrogen, when either of them ponders over the Professor's final reaction which, as nearly as we can give it, is

PRODUCT TOO STRONG FOR A FORD CAR

The question was raised whether Henry Ford knew about this process, and it appears that he is not only thoroughly informed but that he is having a special truck designed for economical hauling with it. Then somebody wanted to know whether the gasoline had been thoroughly tested out with automobiles. "I should say it had," responded the Professor. "Charlie," he commanded, "come over here and tell this gentleman about that test we made the other day." "Well, sir," said Charlie, "we mixed some of it up with ordinary Standard Oil gasoline, fifty-fifty, and they drove a big car seventy-five miles on 3 gal. of it!" Then Charlie added a statement which may well induce automobile engineers to pause and consider. He said:

"Our gasoline is *too strong* for the ordinary Ford car."

Everyone present was deeply impressed. One of the investors said: "Professor, this is wonderful. It certainly beats the world. But you've got plenty of peat here. Would you mind making another run for us?"

"No," said the old gentleman. "I'm tired. Once is

enough. What's the matter anyway? Any of you getting skeptical?"

"Oh, no, no. Not in the least. I only thought——."

SKEPTICS TOLD WHERE TO GO

Like many men of genius, the Professor is rather quick on the trigger, for he interrupted the speaker with:

"Look here; if you're getting skeptical you can go plum' straight to hell! I'll not be insulted with doubts. I don't need your money." Then, going over to Charlie, he caught him by the arm and said: "Charlie, if any of these people are getting skeptical they can go straight to hell!" And with that he led the way upstairs to his office.

It lacked only twelve minutes of noon, and at noon the options expired. Try as we will we cannot pry out any information as to what happened before the sun reached meridian. How much was subscribed, or who subscribed, or who let his option lapse, is hidden from us. We have been told that before the "official test" which we have described about \$200,000 had been underwritten and about \$60,000 paid in. We have no knowledge of the commitments which followed the official test, or what became of the California oil men or the group of New York capitalists with their chemist.

One other pearl of information that we have from the Professor is that there is only 2 per cent of ash from peat as consumed by his process and that this is so high in potash and phosphorus that the fertilizer people are literally crying for it. And, aside from the ash, there is no waste, solid, liquid or gaseous, from the operation. "I convert everything," said the Professor. We should say he did!

A New Process of Drying Turf for Fuel in Finland

Consul Leslie A. Davis, of Helsingfors, reports that a Finnish company, called Oy. Hydroturve A. B., has been formed, with a capital of 1,000,000 marks, for the purpose of promoting the hydroturf process of drying turf to relieve the serious fuel shortage in Finland. Similar companies have been organized in Sweden and Denmark.

The new method was invented by engineers working under orders from the Russian Soviet Government to find a more labor-saving method of preparing turf as fuel for the great central power station near Moscow, the process being made known in Finland through an escaping engineer.

The fundamental principle of the process is quite simple. The raw turf in the swamp, by a powerful jet of water under a pressure of 20 atmospheres, is freed from all old roots and changed to thin mud. This is pumped out on a drying field and spread in layers from 20 to 30 cm. in depth. When sufficiently dry it is cut into bricks of uniform size by means of a tractor. The roots are lifted out of the mud by a special crane without interfering with the removal of turf. The turf pump is constructed like an ordinary water turbine, is reversible with aid of electric motor, is equipped with a cutting apparatus which completes the work of the water jet, and can be raised or lowered as the surface of the mud requires. Both the crane and the pump are mounted on a plate-covered car which can be pushed backward or forward on rails along the line of work.

Experiments in Russia demonstrated that the hydroturf dries better in ordinary weather than turf prepared in any other way.

Potash in 1919*

BY W. B. HICKS AND M. R. NOURSE

THE quantity of potash produced in 1919 fell short of the production in 1918, as is shown by Table I. The tonnage from the alkali lakes of western Nebraska continued to exceed that from any other

TABLE I. DOMESTIC POTASH PRODUCED AND SOLD IN THE UNITED STATES IN 1915-19

Year	No. of Plants	Production		Sales		Value
		Crude Potash (Short Tons)	Available Content of Potash (K ₂ O), (Short Tons)	Crude Potash (Short Tons)	Available Content of Potash (K ₂ O), (Short Tons)	
1915.....	5	4,374	1,090	4,374	1,090	\$342,000
1916.....	70	35,739	9,720	35,739	9,720	4,242,730
1917.....	95	126,961	32,573	126,961	32,573	13,980,577
1918.....	128	207,686	54,803	140,343	38,580	15,839,618
1919 (a).....	77	110,243	30,845	173,786	46,732	11,370,445

(a) Production for 1919 includes a quantity of material either utilized by producer or reported as not marketed; sales for 1919 include material produced in 1918 but sold in 1919.

region or source. At the beginning of 1919 about twenty plants in this region were ready to operate, but only eight of these reported production.

Other producers from salines are American Trona Corporation and the Solvay Process Co., both at Searles Lake, Cal.; the Utah-Salduro Co., Salduro, Utah; Salt Lake Chemical Co., Burmester, Utah, and the Salt Lake Potash Co., Kosmo, Utah.

In the Marysvale region, Utah, the Mineral Products Corporation continued production from alunite in 1919. Some potash alum was produced by one company from alunite, and several companies are known to have shipped raw and calcined alunite either for experiments or for incorporation in fertilizers. The mill of the Florence Mining & Milling Co. was used by several companies for experimental purposes.

Silicate rocks as a possible source of potash continued

to receive attention. The plant of the Liberty Potash Co., at Green River, Wyo., which utilized the potash-bearing rocks of the Leucite Hills, was completed during the year and operated for a short time in November and December, but was closed on account of technical difficulties. A plant for the extraction of potash from green sand was constructed by the Eastern Potash Corporation on Raritan River near New Brunswick, N. J., but no production was reported.

In the early part of 1919 eighteen cement mills had potash-recovery plants installed or under construction. Of this number fourteen were in operation, several for only a part of the year. Several discontinued the production of potash at the end of the year.

Only one kelp plant other than the experimental plant of the Bureau of Soils, United States Department of Agriculture, at Summerland, Cal., reported production of potash in 1919.

TABLE II. POTASH PRODUCED IN THE UNITED STATES IN 1919, CLASSIFIED ACCORDING TO SOURCES.

	No. of Plants	Crude Salts (Short Tons)	Available Potash (K ₂ O), (Short Tons)	Percent-age of Total	Total Value
Natural brines:					
Nebraska lakes.....	8	35,733	9,022	29.2	\$1,890,302
Other brines.....	6	32,385	11,293	36.3	2,875,908
Alunite.....	14	68,118	20,315	65.8	4,766,210
Dust from cement mills.	6	6,594	2,293	7.4	683,055
Molasses distillery waste	14	11,567	1,159	3.8	233,977

(a) The figures in this table were compiled from the records of the Bureau of Foreign and Domestic Commerce, United States Department of Commerce, by recalculation to short tons and to actual potash (K₂O), and by giving the totals for calendar years instead of fiscal years. The tons are calculated to the nearest even unit and the values are those given in the original records, so that the value given for a high-priced commodity received in small quantity may not be strictly applicable to the quantity given. For instance, 2,705 lb. of cyanide received in 1916 is reported as 1 ton, but the value given is that of the actual quantity received. Furthermore the values are those placed on the commodities by the shippers, and represent the values at point of shipment, and do not agree with market quotations in this country.

() Used principally in fertilizers. (c) Pounds. (d) Used principally in chemical industries.

Mechanism of Solidification of a Copper:Aluminum Alloy

A Study of Piping, Segregation and the Mechanism of Solidification of Cu:Al Alloys (Especially No. 12 Containing 8 per Cent Aluminum) by Means of Precision Measurements on Density at Various High Temperatures

By JUNIUS DAVID EDWARDS
Physical Chemist, Aluminum Company of America

IN AN earlier paper¹ the experimental methods were described and measurements of the density of aluminum over a wide range of temperatures were given. The same methods have been applied to an investigation of the copper:aluminum alloys, rich in aluminum. Although these measurements were made for a specific purpose, they yielded as a byproduct many interesting and suggestive theories regarding the casting of alloys in general. These will be developed somewhat in detail as illustrating the practical bearing of such measurements on the casting of aluminum and its alloys.

The density of the solid metal was determined by weighing in water and air; the density of the liquid metal was obtained by the densimeter method described in the preceding paper. Most of these measurements were carried out by T. A. Moormann.

RESULTS OF DENSITY DETERMINATIONS

In Table I are given the results of density determinations of alloys containing approximately 8, 30 and 60 per cent copper. The aluminum used as the basis of these alloys averaged 99.4 to 99.5 per cent aluminum. The copper was electrolytic copper of high purity. The solid specimens for the density determinations were chill cast in a small graphite mold. This method of casting gives a uniformly dense material in the sense of being as free as possible from voids and pores. The alloys tested cover the range for which the density was desired and permit reasonably accurate interpolation of intermediate values.

The observed values were plotted on an ample scale and the values for convenient temperatures as given in Table II were interpolated from these graphs. The greatest deviation of the observed values from a straight line fitted to them is only about 0.1 per cent.

In order to show the relation between density and composition, a series of isotherms for 20, 700, 800, 900

1,000 deg. C. have been given in Fig. 1. From these curves the density of compositions other than those given in the table can readily be obtained. A portion of

¹"Density of Aluminum From 20 to 1,000 deg. C.," CHEM. & MET. ENG., vol. 24, No. 2, p. 61, Jan. 12, 1921.

THE SPECIFIC VOLUME OF SOLID COPPER:ALUMINUM ALLOYS

Although there is no direct relation between density and composition, the specific volume (reciprocal of the density) of the copper:aluminum alloys is very nearly a linear function of the composition over quite a range. This relation is illustrated in Fig. 2, where the density and specific volume are each plotted as functions of the composition. The specific volume data are very well represented by a straight line—at least in the region 0 to 60 per cent aluminum where we worked. Some of the published data in the region 90 to 100 per cent copper deviate from the linear relation.

In a heterogeneous mixture of two substances one would expect the specific volume of the mixture to be a linear function of the composition. In the system copper:aluminum, there are at least two compounds formed (CuAl_2 and Cu_3Al) and a number of fields of solid solution. The effect of these additional phases, however, in causing the specific volume to deviate from a straight line is apparently quite small, except in the copper-rich alloys as previously noted.

This relation offers a useful method of calculating the approximate specific volume (or density) of the solid alloys at temperatures up to their melting points. The expansivities of aluminum and of copper are quite well known, and their specific volumes at any temperature can therefore be calculated with reasonable accuracy. Then if the linear relation still holds for their alloys at this temperature, the specific volume of the latter can readily be calculated.

For example, the specific volumes of copper and aluminum at 20 deg. C. are $1 \div 8.90$ and $1 \div 2.703$ respectively. The specific volumes at 540 deg. C. are calculated from the expansion formulas to be 0.1157 and 0.3860. The specific volume of the alloy containing 32 per cent copper (the eutectic) is then $0.32 \times 0.1157 + 0.68 \times 0.3860 = 0.2995$, and its density is $1 \div 0.2995$, or 3.33, at 540 deg. C. This value may be checked in another way. An approximate determination of the total linear shrinkage from 540 to 20 deg. C. of an alloy of this composition gives a value of 0.15 in. per foot. The cubical expansion (20 to 540 deg. is then $1 + (0.15 \div 12.00) \times 3 = 1.0375$. The density of the eutectic mixture at 20 deg. is 3.46 and its density at 540 deg. equals $3.46 \div 1.0375 = 3.33$, which is the same value as calculated by the method of specific volumes. It seems probable that the values for solid alloys calculated from the specific volumes of the component metals and their expansion are accurate to at least 1 per cent for the alloys under consideration.

The phenomenon of growth or the production of permanent volume changes in aluminum alloys by heating to 300 deg. C. and over seems well established (see article by Zay Jeffries, *J. Soc. Aut. Eng.*, vol. 7, p. 295, 1920). The measurement and interpretation of such changes would logically be a part of a complete investigation of the density of the solid at temperatures up to the melting point, but they have not been undertaken as yet.

No. 12 ALLOY

The alloy containing 8 per cent copper and known as No. 12 alloy is so generally used for casting purposes that it is of interest to give it a more detailed discussion.

Density at 20 Deg. C. The density of the cast 8 per cent copper alloy is about 2.86. Although the specimen which had this density was apparently sound and free

from holes, it is probable that working would increase the density somewhat due to the elimination of microscopic voids. It is, however, representative of a sound ingot of this composition. For reasons which will be discussed later, No. 12 alloy cast under certain conditions may be somewhat porous and such metal will have a correspondingly lower density. Samples have been examined running as low in density as 2.80 or 2.75, but examination under the microscope revealed the presence of voids between the grains. As used, No. 12 alloy may vary from 7.0 to 8.5 per cent of copper; its

TABLE III. COMPOSITION AND PROPORTIONS OF SOLID AND LIQUID IN EQUILIBRIUM IN NO. 12 ALLOY

600	2.2	19.0	66	34
560	3.6	28.0	82	18
540	4.3	32.0	86-100	14-0

Fig. 2. Specific volumes of copper:aluminum alloys; equilibrium diagram (upper figure).

density, according to Fig. 1, will vary from 2.84 to 2.87. The commercial alloy usually has a higher iron and silicon content, which will tend to raise the density slightly. Taking into consideration all of these factors, the density range of No. 12 alloy may be placed at 2.82 to 2.88 at 20 deg. C.

Course of Freezing With Copper:Aluminum Alloys. To understand the process of freezing of No. 12 alloy, it is instructive to consider the equilibrium diagram as shown in Fig. 1. The main features of this diagram are taken from the work of Carpenter and Edwards² with

²Proc., Inst. Mech. Eng., p. 57 (1907).

some slight modifications. The alloys containing less than 32 per cent copper are the only ones of interest in the present connection, and it is this portion only of the diagram which need be considered. The alloy containing 8 per cent of copper begins to freeze at 636 deg. and the freezing is completed at 540 deg. These temperatures are given by the points of intersection of the vertical line *ad* at 8 per cent copper with the liquidus and solidus curves respectively. The first crystals to separate at 636 deg. have the composition given by the intersection of the horizontal line *ab* through this point with the solidus curve at *b*. The limit of solubility of copper in aluminum as CuAl_2 is reached at 4.3 per cent copper (Merica)³ and crystals of this composition are in equilibrium with liquid of the eutectic composition (32 per cent copper) at 540 deg. The relative proportions

of liquid and solid are then $\frac{cd}{ce}$ and $\frac{de}{ce}$. The composition

of liquid and solid in equilibrium at any other temperature in the freezing range is given by the intersection of the horizontal temperature line with the liquidus and solidus curves, and the relative proportions by the inverse ratio in which the vertical line at 8 per cent copper divides the horizontal distance between the solidus and liquidus. In Table III certain of these values as calculated from the diagram are tabulated. It is recognized that the solidus curve in particular has not been determined with any great accuracy and that these values calculated from the diagram are subject to revision as more accurate data on the equilibrium relations are obtained.

Fig. 3. Comparison of the rate of separation of solid from the 8 per cent copper:aluminum alloy with an inverse rate cooling curve of the same alloy.

In the course of cooling, when the temperature of 540 deg. is reached, about 86 per cent of the metal has crystallized and the remaining 14 per cent of liquid has the eutectic composition. This eutectic liquid then freezes at constant temperature, as in the case of a pure metal. The above data are for the condition of equilibrium

which can only be approximated by extremely slow cooling. The effect of more rapid cooling is to prevent equilibrium being reached at any temperature, between the crystals already formed and the liquid. One result of this failure to reach equilibrium will be to increase the proportion of eutectic present at 540 deg. C.

It is obvious from the data of Table III that the solid separates most rapidly during the first part of the freezing and the rate gradually decreases as the eutectic temperature is approached. This is shown graphically by the dotted line curve in Fig. 3, in which the rate of crystallization, expressed in grams of solid separating per 100 g. of metal, for each 2 deg. fall of temperature is plotted as a function of the temperature. There is also given for comparison an inverse rate cooling curve (solid line curve) of No. 12 alloy as determined in this laboratory. Since the time required for the melt to cool any interval, such as 2 deg., is a measure of the

Fig. 4. Density of solid and liquid in equilibrium at different temperatures; also per cent of solid present at equilibrium.

amount of solid separating, the two curves are substantially equivalent and the agreement between the theoretical and observed rates is quite satisfactory.

There are two points in connection with the inverse rate curve which require further mention. At about 577 deg. there is a point of inflection corresponding with the separation of the silicon as a eutectic mixture with aluminum; the constituents classed as impurities were not considered in connection with the equilibrium diagram, so there is no corresponding point on the dotted curve. The observed eutectic temperature is depressed several degrees; this phenomenon is frequently observed where the eutectic is present in relatively small proportions.

From the observed data and by the methods already discussed the density of the solid and liquid in equilibrium with each other at any temperature can be ascertained and they have been plotted in Fig. 4. There is also plotted the relation between the amount of solid and liquid present in equilibrium at different temperatures. These curves indicate several very significant facts. It will be noted that the first crystals formed, at 636 deg. C., are heavier than the liquid from which they separate and consequently they tend to sink. The crystals which separate have, however, less copper than the liquid and copper concentrates in the liquid; as a result, the liquid increases in density faster than the solid. They become equal in density at about 630 deg. when approximately 25 per cent of the liquid has crystallized. At all temperatures lower than 630 deg. the graph shows the crystals to be lighter than the liquid

³Bureau of Standards, Scientific Paper No. 337 (1919).

and they consequently tend to float. The consequences of this relation will be considered in the succeeding paragraph.

Segregation in No. 12 Alloy. In the course of an examination of various small experimental ingots of No. 12 alloy it was noticed that there was considerable variation in the copper content and density of different parts of the same sample. The copper content increased from top to bottom of the ingot and the density increased in the same manner. Such segregation was marked in large ingots which had cooled very slowly. Because of the difference in density between crystals and liquid, as shown in Fig. 4, it is not surprising that segregation should occur with this alloy and that the region of highest copper should be at the bottom of the ingot. The rate of cooling and shape and size of the mold will largely determine the amount of segregation which will occur.

The difference of density between crystals and liquid may be indirectly a cause of porosity in castings. For example, if a large mass of crystals is floating in the liquid, they may form a network which gains considerable rigidity as freezing nears completion. Consequently, when the eutectic solidifies, there is a tendency for it to withdraw downward from the interstices of this network and leave voids between the crystals unless additional fluid eutectic metal is supplied. Such behavior tends to reduce the apparent size of the pipe by converting the upper part of the ingot into a porous mass. Microscopic examination has demonstrated the existence of these voids caused by the withdrawal of eutectic, and

as with pure aluminum, which gave the value 6.6 per cent. The relative piping effect with the pure metal and the alloy is, however, quite different. The reasons for such a difference will be developed later.

SUMMARY

The density of a series of copper:aluminum alloys has been determined for the solid metal at 20 deg. C. and for the liquid metal at temperatures ranging from the freezing point to 1,000 deg. C. By the employment of the expansion data for the solid metal and by several methods of interpolation the density of any alloy containing between 0 and 60 per cent copper can be estimated with a fair degree of accuracy for temperatures from 20 to 1,000 deg. C.

These data taken together with the thermal equilibrium diagram for the system copper:aluminum have furnished some very interesting information regarding the volume changes occurring in the copper:aluminum alloys during freezing. They have been discussed with particular reference to the 8 per cent copper alloy and furnish a very reasonable explanation of piping, segregation, etc., as observed with No. 12 alloy.

Perfumery Industry in France

Grasse, a small city in the mountains about twenty-five miles from Nice, is the center of the French perfumery industry. The commodities manufactured at Grasse are the primary products of perfumery, such as floral concretes, essential oils and enfleurage grease. In 1919 the demand for these articles was so large that their prices increased, and even at the higher prices the manufacturers were not able to fill their orders. It is said that the percentage of profit on the turnover was comparatively smaller than before the war, however.

The manufacturers point out that the price of flowers has taken an incredible flight since the war. Violets advanced from 5 fr. (1 fr. = 19.3c. normally) per kilo (1 kilo = 2.2 lb.) in 1914 to 10 and even 12 fr. per kilo in 1919; roses, from $\frac{1}{2}$ fr. to $3\frac{1}{2}$ fr.; jasmine, from 1 fr. to $7\frac{1}{2}$ fr.

Wages for women increased from 4 to 9 fr.; for men, from 5 to 12 fr. In the Grasse manufacturing plants about 80 per cent of the work is done by women. Wages for skilled labor also increased. Coal and alcohol, the latter being extensively used in the manufacture of perfume, are difficult to obtain even at high prices, so that although the selling price of the primary articles of perfumery has increased, it has not advanced in the same proportion as the costs of production.

Alcobronze, a New Copper: Aluminum Alloy

A new alloy of copper and aluminum has been invented and tested by the Aktiebolaget Skandinaviska Armaturfabriken. The name given to the new combination is "Alcobronze." It has the color and luster of gold, and it is said to be stronger, tougher and harder than any other bronze. It is further stated that it can be wrought, forged or rolled in any way without suffering deterioration, and that it resists the action of the air, acids and salt water, being therefore particularly suitable for ships' forgings, propellers, condensers, machine parts, bearings, surgical instruments, skates, ornaments, etc.—*The Engineer*, Dec. 17, 1920.

Fig. 5. Density of aluminum and of the 4 and 8 per cent copper:aluminum alloys from 20 to 1,000 deg. C. Dotted portions of the graph are calculated. (See text.)

density determinations combined with chemical analyses have given further proof of their extent. The presence of such voids is prevented in commercial foundry practice by the use of suitably designed gates and risers which supply the necessary liquid metal.

Shrinkage of the 8 Per Cent Copper Alloy. From the data of Table II and by the methods outlined for the calculation of the specific volumes of the alloys at temperatures up to the melting point, the complete density curves of Fig. 5 were constructed. The average density of the mixture of solid and liquid present during the melting range was calculated from their calculated proportions and density (cf. Table III). The contraction in volume of No. 12 alloy from the beginning to the end of freezing (636 to 540 deg. C.) is about 7 per cent. The solidification shrinkage is therefore about the same

The Chemistry and Manufacture of Satin White*

BY A. COBENZL

SATIN white is a calcium aluminate mixed with hydrate calcium sulphate. It is a very important white pigment and is of particular value in the manufacture of coated paper, as well as in the preparation of alumina lakes.

The chemical reactions which take place in the preparation of satin white, as well as those responsible for the formation of alumina lakes, have been expressed usually by empirical chemical formulas; but the physical conditions and factors attending these reactions have been neglected entirely, almost intentionally, it would appear. The importance of conducting the operations under the most advantageous physical conditions was not appreciated or understood. It was all a matter of following blindly old-established directions, which were guarded most zealously and carried out to the letter.

Very often the product, although correct according to the chemical equation, was nevertheless valueless, because the physicochemical conditions under which it was made were not right. Satin whites which were found to be identical by quantitative chemical analyses have shown very different physical properties and we must look to colloidal chemistry for the true explanation of these phenomena.

THE "RULE-OF-THUMB" PROCESS

The author was called upon to supervise the operation of a factory making satin white. He was given the operating information and was told to follow this to the letter. He was warned to continue using the same raw materials, to obtain them from the same source of supply and not to make any change whatever in the long-established practice of the plant. The directions received for making satin white were:

Eighty-five kg. of caustic lime is dissolved in about 200 liters of boiling water. The volume is brought to 450 to 500 liters by the addition of more water and the solution is passed through a fine-meshed sieve. The cold solution is then pumped into a powerful churn of about 1,500 to 1,600 liters capacity. A cold solution of 125 kg. of aluminum sulphate (containing 18 per cent Al_2O_3) in 500 liters of water is added quickly, with vigorous agitation. The mixture is heated strongly until the mass became very viscous. The excessive rise in temperature due to the exothermic reaction and the difficulty in stirring due to the thickening of the mass are obviated by adding water up to about 1,100 to 1,200 liters. The mass, which was pasty at the beginning, is changed gradually into a uniformly viscous sirup, which can be drawn out into lustrous threads. The sirup is pumped into a 7,000-liter capacity vat, provided with stirring apparatus and well mixed with water, until the volume reaches 5,500 to 6,000 liters.

The end of the operation is reached when a sample of 100 c.c. of the filtered solution requires no more than 24 to 26 c.c. of a N/10 oxalic acid solution for neutralization with phenolphthalein as an indicator. If this test shows a higher degree of alkalinity, add 4 kg. of H_2SO_4 (40 deg. Bé.) and bring the solution to the proper degree of alkalinity by the further addition of aluminum sulphate.

To avoid the yellow coloration of the product, the various materials used in the manufacture must be as free as possible from iron. The last traces of any yellow color visible to the naked eye are neutralized by the addition of indanthrene blue, 2GSZ of the Badische Anilin- und Soda-Fabrik, in the form of a solution of 250 g. of the commercial pasty dyestuff in 5,000 c.c. of water. From 100 to 150 c.c. of this solution is usually required for each charge. The satin white is then separated from the solution by filtration.

THE CHEMISTRY OF THE PROCESS

The chemical reaction was represented by

but a closer examination of the progress of the operation and the several observations on the chemical conditions surrounding the same have shown that this equation is fundamentally false and that the actual equation of the reaction gives a calcium aluminate with hydrated calcium sulphate according to the equation

Properly made satin white is a pure white lustrous mass which when added to water becomes gradually a finely pulverized mass and which when suspended in the liquid settles with difficulty.

To test the product for its free alkali content, 50 g. of the mass is agitated with 300 c.c. of water and 100 c.c. of the filtrate is titrated with N/10 oxalic acid solution. A good product should require for neutralization about 1.5 c.c. of this acid solution—that is, about 7 c.c. per 100 g. of the original mass.

The moisture content has to be determined by drying on a water-bath that is at a temperature not exceeding 100 deg. C., because at a higher temperature the hydrated calcium sulphate ($\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$) loses its water.

The proportion of calcium corresponding to the aluminate is found in the most accurate manner when a weighed quantity of the mass is mixed with water and titrated with N/2 HCl solution, using phenolphthalein as indicator, until the solution is decolorized permanently.

The total lime, alumina and H_2SO_4 can be found accurately by the regular gravimetric methods. Analyses for moisture, calcium (corresponding to the aluminate) and free alkali are all that is necessary for routine control of the process. The average analysis of satin white is:

	Al_2O_3	CaSO_4	CaO
Found	5.06	18.47	8.06
Calculated from $\text{Al}_2\text{Ca}_3\text{O}_6$	5.00	20.00	8.23

The great discrepancy between the CaSO_4 percentages found and calculated is due to the fact that usually the $\text{Al}_2(\text{SO}_4)_3$ employed does not have the required alkalinity.

IMPORTANCE OF THE ALALINITY OF THE $\text{Al}_2(\text{SO}_4)_3$ EMPLOYED

The lime used in the manufacture of satin white must be very pure, white, free from iron, sand and carbon, must slake quickly and give a pure, white and porous hydrated lime. The sulphate of alumina to be used should contain about 18 per cent Al_2O_3 and only 80 to 85 per cent of the theoretical quantity of H_2SO_4 corresponding to the Al_2O_3 present. The insoluble matter (silica) is not to be over 0.4 per cent and the iron content, at the most, 0.005 per cent. The use of aluminum sulphate containing more than the above corresponding amount of H_2SO_4 is harmful.

In one case, when production was being forced, an

*Abstracted and translated from *Chemiker Zeitung*, Sept. 7, 1920, pp. 661-662.

aluminum sulphate of undetermined alkalinity was used. A preliminary examination indicated that there was no reason why a good product should not be obtained, as the sulphate seemed to be of the best quality and equal to the standard brand, in outward appearance at least. But the results were very bad. The mass became very viscous in the stirring apparatus and eventually it was necessary to stop the operation and break up the hardened mass with hammer and chisel. A laboratory experiment was made to determine why this happened. It was found that the new sulphate was just as good as the standard material in every respect but one—viz., that the former contained almost the total calculated quantity of H_2SO_4 corresponding to the alumina content of the sulphate, hence more than the appropriate 80 to 85 per cent of the theoretical amount of H_2SO_4 .

CONTROL OF THE H_2SO_4 CONTENT OF THE ALUMINUM SULPHATE

The H_2SO_4 content of the sulphate solution can be controlled easily by the addition of milk of lime. The $CaSO_4$ found settles and has to be separated. If it is allowed to remain suspended in the solution, then, strange as it may seem, no satin white is formed, but the reaction proceeds according to the equation

until a solid mass is formed. The explanation of the phenomenon seems to lie within the realms of colloidal chemistry. It is known that the presence of a pure crystalline (in this case $CaSO_4$) will prevent the formation of the colloid—viz., will hinder coagulation. The entire question was investigated in the laboratory and the results obtained therein have been applied to actual practice with good results.

About 2,750 kg. of the sulphate which gave the above negative results is placed into a perforated basket and suspended in a vat provided with a stirring device and containing about 6,600 liters of water. The salt is dissolved in a few hours without any further treatment. Milk of lime, made by slaking 80 liters of caustic lime with 250 liters of boiling water, is then added with constant stirring. After about one hour the stirring apparatus is stopped and the clear liquor decanted. This liquor shows a gravity of 25 deg. Bé. and can be used successfully in the usual way for making satin white. This process of de-acidifying is unprofitable, especially in plants that manufacture their own aluminum sulphate. Therefore a process for obtaining a sulphate of the proper H_2SO_4 content directly from $Al(OH)_3$ has been developed. This consists in treating in lead-lined pots the aluminum hydroxide obtained from bauxite with a quantity of 50 to 52 deg. Bé. H_2SO_4 (the Al_2O_3 content of the press-cake is first determined very accurately) sufficient to neutralize about 80 to 85 per cent of the Al_2O_3 . The mass becomes heated up to 106 to 107 deg. C. by the heat generated during the reaction and kept at 108 deg. C. until the mass becomes viscous. This substance when dissolved in water up to a 25 deg. Bé. solution can be used successfully in the regular process of satin white manufacture.

EXPERIMENTS INSTITUTED TO PROVE THAT CALCIUM ALUMINATE IS ACTUALLY FORMED

Pure $Al(OH)_3$ in the moist condition just after being made is intimately mixed in a mortar with slightly more than the theoretically calculated quantity of a milk of lime. At first the mixture becomes almost solid, but by continuing the mixing it becomes soft, then a

fluid of such consistency as to be capable of being drawn into threads, exactly as happens in the process of making satin white. When this mass is stirred up with water, it settles easily. In order to eliminate the excess of lime, the mass is washed with water several times until 100 c.c. of the final wash water can be neutralized by not more than 3 c.c. of N/10 oxalic acid, when it may be considered that all the excess lime has been washed out. The analytical results indicated that Ca content in relation to the Al content is somewhat less than the calculated value from the aluminate. When the aluminate is treated with an excess of water it is partly decomposed and some $Ca(OH)_2$ is found in the solution. When freshly precipitated $Al(OH)_3$ is treated with lime water at normal temperature no change takes place even after long standing, but at boiling temperature the reaction takes place rapidly and the product obtained is calcium aluminate.

COLLOIDAL CHEMISTRY AND THE SATIN WHITE LAKES

The chemical investigation of the satin white manufacturing process, from the standpoint of colloidal chemistry, was not only instrumental in explaining the technology of this process, but also had an important bearing on the formation of alumina or alumina-lime lakes. The statement is found in printed literature that the alumina-lime process for forming lakes is uncertain and will not always give good results; but the author has found that there is scarcely a more dependable process to be found. All that is necessary to obtain good quality lakes is to work out the process in accordance with the equation

as given above for the preparation of satin white.

When satin white, still in the liquid condition in the agitator, is transformed into the unfilterable state, the colloidal particles are from 0.0001 to 0.000001 mm. in size. To be filtrable, the satin white must be coarser than 0.0001 mm. It is well known that as the dispersion of the colloidal substance increases the surface area increases.

A cube, having sides 1 cm. in length and a surface area of 6 sq.cm., cut up into cubes, having sides 0.0001 cm. in length, will give 10^{15} cubes with a surface area of 60 sq.m., and by further subdivision into cubes having sides 0.000001 mm. in length will give 10^{21} cubes with a surface area of 6,000 sq.m. This means that 1 g. of a pigment in a colloidal dispersion could cover a surface of about 600 sq.m. Nature itself shows us best how the most brilliant colorations are obtained with almost infinitesimal quantities of coloring matter. It is well known in dyestuff technology that coarsely grained dyes are without gloss and are lifeless. Hence it follows, as has been proved by actual experience, that satin white in the proper state of colloidal dispersion gives lakes of surpassing brilliancy in color.

THE AUTHOR'S PROCESS OF MAKING SATIN WHITE

Laboratory research has enabled the author to devise a process of making satin white. The principle of the process briefly stated is:

About 90 g. of lime is slaked in 220 c.c. of boiling water. To this solution add quickly 130 g. of finely pulverized (260-mesh sieve) $Al_2(SO_4)_3$ of the proper degree of acidity, as explained above. The mass is heated until it becomes almost solid, when 250 c.c. of water is added and the mixture agitated thoroughly. The resulting product is a very good quality satin white.

BY WELLINGTON GUSTIN

Sympathetic Strike to Compel Employment of Union Men Only Held Unlawful

A contract of employers with labor unions to employ only union men was held to be against public policy by the New Jersey Court of Chancery in an injunction sought by the Lehigh Structural Steel Co. and others against the Atlantic Smelting & Refining Works and others.

The Lehigh company contracted to fabricate and deliver to the Atlantic Smelting & Refining Works the steel for a building at Brills, Newark, N. J., and also to erect it. The erection was sublet to the Donnell-Zane Co. The work had been nearly completed when the erectors struck. The Donnell-Zane Co. decided to employ non-union labor, and was notified by a representative of the Atlantic company that it would not be permitted to finish the job with other than union workmen, the reason being given that there would be a general strike of the allied trades on the works if it were done otherwise.

The court said that the strike was called, and that the fact was not disputed that a general strike, in sympathy, would have been brought into play to force the Atlantic company to breach its contract with the Lehigh company if Donnell-Zane persisted in defying organized labor.

CLOSED SHOP THE ISSUE

The complainants set up that the strike was ordered to force them, against their will, to conduct their business on the closed-shop plan. The business representatives of the unions admitted this to be the avowed purpose and pleaded in justification that the Building Trades Employers' Association of New York City (comprising nearly all the building contractors of New York), of which the Iron League is a member, entered into a contract with the New York Building Trades Council of Greater New York and Long Island (an association of all the trades unions of those localities) whereby the employers' association bound its members to employ only union men in their various building enterprises in Greater New York and certain named additional territory.

The complainants admitted the making of the contract and their refusal to abide by its terms, claiming it was beyond the power of the employers' association to bind the Iron League and its members, restricting them in selection of their workmen to members of organized labor, because it was in contravention of public policy, and therefore unlawful.

In awarding the injunction against the Atlantic company, the labor unions and others, the court pointed out that the men were not under contract, and individually had the right to quit work as it pleased them, and as members of the federation it was their privilege to use the strike in sympathy and to advance the common cause of organized labor, provided the motive or the object sought to be attained was not an unlawful one. But it was said the privilege to strike was not license to strike. Those availing themselves of the privilege must

respond in damages for the injury inflicted, unless they can show just cause or excuse, and this burden is on them to do so.

A sympathetic strike, merely to force the employer in other territory to comply with the invalid provision of a contract to employ only union men in such territory, is without just cause or excuse, and is unlawful. Also, the court held, the provision of a contract between an association representing nearly all the building contractors of New York City and an association representing the labor unions thereof, binding the contractors to employ only union men in their enterprises therein and having for its object the closed shop, the monopolization of the labor market by the unions, violates public policy as to monopolies.

In the instant case, the Atlantic company urged it was acting in self-defense and feared the wrath of organized labor. In other words, it breached its contract to avert a general strike. But the court said that was not a legal excuse for breaching the contract. The company's protection lies in the law, not in the graces of those who transgress it. The company may have been wholly indifferent as to the success of the strike, but the enforcement of the closed shop at Brills made it a co-conspirator with the union.

Guano Company Held Liable for Unlawful Obstruction to Navigation

A loading crane, erected without permission of the Secretary of War, traveling on a track along the edge of a wharf, and which, although movable, was left at a time when not in use extending 38 ft. over the water of the slip was held to be an unlawful obstruction to navigation by the United States Circuit Court of Appeals, and the owner was held liable for injury to a boat which, without negligence on its part, struck the crane in passing out, in the case of *F. S. Royster Guano Co. vs. Outten*, with the *Pocomoke Guano Co.* as intervener.

The action was brought to recover damages for the negligent maintenance of a loading crane or derrick, erected without making application to the Secretary of War for his approval and which it was claimed constituted an unlawful obstruction to navigation. The crane was left suspended over a barge which it had been unloading. It extended 8 ft. beyond the barge over the water and about 45 ft. high when the *Mannie May*, loaded with fertilizer, collided with it, at the harbor of Norfolk, Va. The master of the vessel recovered \$1,315 damages and the *Pocomoke Guano Co.* was allowed damages of \$699.75, the full amount of its claim, for fertilizer lost when the vessel sank.

The court said any obstruction of a navigable stream must be subordinate to the right of navigation. The derrick or crane, reaching into the air a considerable distance from the water, rendered it all the more difficult for one navigating a vessel to determine accurately as to the proximity of such an obstruction to the top of a vessel. If this crane, after being used, had been immediately turned to one side, so as not to project over the navigable waters, and at all times kept in that position while not being used, it could not have been said to be an unauthorized obstruction. Even if this obstruction had been authorized by the proper authorities, it would have been just as much an obstruction to navigation as would have been a drawbridge left in an improper position when not being manipulated so as to permit vessels to have an easy passage.

Synopsis of Recent Chemical & Metallurgical Literature

Crystal Growth and Recrystallization in Metals—

Prof. H. C. H. CARPENTER and Miss C. F. ELAM presented a noteworthy paper on this subject before the fall meeting of the British Institute of Metals, in which they presented experimental results which cannot apparently be fitted into existing theories. They used an alloy containing 98.5 per cent tin and 1.5 per cent antimony; it is without phase changes, and after annealing is composed of allotriomorphic crystals of homogeneous solid solution. It is exceedingly active in its crystal growth—any polishing or cutting brings about spontaneous recrystallization¹ of a surface layer of exceedingly fine crystals, which may be removed only by alternate polishing and etching in ammonium sulphide. Enough stress remains to induce additional grain growth¹ after annealing at 200 deg. C. for thirty minutes, and the new boundaries are marked by a line which is really a difference in level, and by a distinct tarnish color. These successive contours occur at each arrest in the progress of growth, up to its limit, as is illustrated in Fig. 1. Repolishing gives new boun-

Fig. 1. Five-sided crystal absorbed by its neighbors in six successive heatings. $\times 85$.

Fig. 2. Cast aluminum annealed ten weeks at 550 deg. C. $\times 85$.

Fig. 3. Same as Fig. 2 after rolling and annealing ten weeks at 550 deg. C. $\times 85$.

daries identical with the most advanced lines; others vanish.

This is evidently an instance of grain growth. Similar experiments show that some rapidly growing crystals often grow in one direction very slowly; a crystal may disappear entirely in one anneal; growth may be halted for one anneal and later resume; growth near the end of absorption is relatively rapid; but in all cases growth is by gradual boundary extension and never by welding another crystal *en bloc*.² Chappell's idea² that similar orientation is necessary for grain growth is disproved by observations that one crystal may be absorbed simultaneously by several neighbors, each of a different orientation as revealed by the etching tone. The often-expressed hypothesis that difference in crystal size is necessary for grain growth, and Jeffries' theory³ that the smaller crystal is absorbed is controverted by the

now observed fact that the growth is not confined to large crystals—of two small ones in the same field one may grow while the other disappears. Indeed, a crystal has been observed to grow at one boundary and be invaded on another at the same time.

Strains induced by successive delicate polishing and etching are certainly small, and it would be important to find out whether, lacking even this amount, crystals would grow upon annealing. Castings often show non-homogeneous dendrites, a structure which obscures the crystalline boundaries, even though they are marked by segregates. Fig. 2 shows the structure of a cast aluminum ingot after having been annealed ten weeks at 550 deg. C. The boundaries are still outlined by FeAl, and other impurities; since the latter have not melted during the heat-treatment and are insoluble at that temperature, they cannot have moved, therefore the presumption is that neither have the original boundaries changed. Fig. 3, on the other hand, shows a portion of the same ingot, rolled and annealed. The boundaries are now independent of the impurities (an observation typical of pure sheet metal) due to the combined action of recrystallization and grain growth. This experiment is thought to prove definitely the wide assumption that recrystallization and grain growth in a non-allotropic metal is dependent upon previous strain.⁴

Given the fact that some strain was necessary for growth, the effect of various deformations was studied

by squeezing or scratching the Sn:Sb alloy, by pulling aluminum sheet various amounts, and by pulling a tapered test-piece of α brass, all indicating that:

1. On moderate strain, slip-bands or twins or both may be produced, giving a certain permanent deformation. On annealing slip-bands and most of the twins are reabsorbed without change in crystal size or shape.

2. A further amount of deformation causes growth of some of the existing crystals upon annealing, a direct growth of pre-existent grains involving no recrystallization. A few twins may persist. However, growing crystals do not invade unstressed regions.

3. All deformation beyond a certain fixed amount causes recrystallization. This is always followed by crystal growth from these new centers if sufficient time at high temperature be given. This growth does not involve a disintegration of the previous crystals, but their gradual reabsorption into the new ones (growing usually from the old boundaries). There is no evidence

¹The authors distinguish carefully between recrystallization and grain growth. Recrystallization involves a complete reorientation of a crystal or group of crystals. It starts from new and independent centers, and in its early stages at least involves refinement in size. Crystal growth, on the other hand, involves the absorption of a crystal by its neighbors, involves increase in grain size, and does not require previous "recrystallization" as defined here.

²J. Iron and Steel Institute, 1914, vol. 1.

³J. Institute of Metals, vol. 20, 1918, II.

⁴Guillet (*Revue de Metallurgie Memoirs*, 1913, vol. 10, p. 1130) describes a nickel brass (Cu 49.52; Ni 2.28; Fe 0.10) which exhibits a single constituent, and develops a coarsely polyhedral grain on reheating, following no working of any kind.

that stress beyond the critical amount necessary for recrystallization causes any reorientation of the former crystals.

Temperature and time are both factors in determining the boundaries of 1, 2 and 3, above. Carpenter and Elam's results check those of other investigators, as follows: The largest crystals are always formed after the minimum stress which induces growth at a given temperature. The lower the annealing temperature, however, the greater the requisite stress.

Strain being necessary for grain growth, and cold work being presumed to increase the amount of amorphous material in the metal, it is only natural to associate amorphous metal and recrystallization. However, the authors found that a cold-worked piece of aluminum, annealed sixty-five hours at 350 deg. C., lost all its acquired hardness (amorphous metal), yet showed no change in grain size. Reannealing at higher temperatures, however, gave exactly the same growth as another piece strained similarly but not softened.

It has been often suggested that structural equilibrium will ensue only when a piece of pure metal consists of one large crystal, but this limit has never been observed. In fact these experiments, involving annealings for a year's time, show a definite end to the growth short of this ideal. In view of the relations 1, 2 and 3 listed above the authors suggest that a certain critical strain is needed before any crystal will grow (a strain which varies inversely as the annealing temperature). Crystals strained below this point will be absorbed; unstrained crystals will show no change whatever. It follows that the less the total strain on a piece the fewer crystals will be strained the critical amount, the fewer the number of growing crystals and the larger their ultimate size. Now in order to have the mass converted into one crystal all the original ones must have been somewhat strained, but only one above the critical amount, not an unimaginable condition, but well-nigh impossible.

Whatever forms of energy operate during the growth or recrystallization of a crystal on heating, the authors' conclusion is that the energy is imparted during deformation. It apparently cannot be stored in amorphous films, nor can it be stored in amorphous crystalline cement, since castings are permanent.

Thermal Analysis by Differential Method.—It may be remembered that Roberts-Austin devised a useful method of determining the presence of small evolutions or absorptions of heat by comparing the rate of temperature change in the body under study and another body having no thermal discontinuities in that region. ARTHUR W. GRAY* described an interesting modification for moderate temperature ranges where the bulb of a precise mercurial thermometer serves as the neutral body. Bound close to this by several layers of silk is one junction of a copper-constant and thermo-element; the opposing junction is inserted into the fine-drawn tip of a glass tube, sheathing both thermometer and couple. This glass tip is inserted through a hole in the specimen under study, the whole arrangement wrapped in asbestos and heated and cooled in an electric tube furnace. With thermocouple attached to a Leeds & Northrup Type P galvanometer, readings of 0.01 deg. C. were easily obtained. Plotting temperature differences between specimen and neutral against temperatures of the neutral (readings of the thermometer) gives very clear indications of transformations in the bodies under study.

*"Transition Phenomena in Amalgams," Columbus meeting, A.I.M.E. (Institute of Metals Division), October, 1920.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office Southampton Buildings, Chancery Lane, London, England.

Color Photography.—Methods are described for producing multicolor grain screens in which the colors are produced partly by spraying a base with colored dyestuffs and partly by immersing the film in other dyestuff baths. The immersion treatment may affect the parts already colored by spraying or the sprayed colors may be utilized as a resist and subsequent to immersion in another colored bath be washed away and all the colors produced by such successive treatments. (Br. Pat. 152,002; not yet accepted; P. FAULSTITCH, Leipzig; Dec. 15, 1920.)

Nitric Acid.—Nitric acid up to 55 per cent strength is obtained by absorption of dilute nitrogen oxides in water absorbed in fibrous substances such as glass-wool or asbestos, or, if the strength does not exceed 50 per cent, cotton may be used. The acid may be expressed from the absorbent fibrous material, or the process may be made continuous by supplying a small stream of water to the fibrous material contained in a tower or chamber while the current of gas is passing, and drawing off the acid at the bottom. (Br. Pat. 152,031; not yet accepted; SOC. L'AZOTE FRANÇAIS, Paris; Dec. 15, 1920.)

Thorium Salts.—An insoluble compound of thorium is obtained by heating a material such as monazite sand in which thorium and phosphoric acid are associated with fuming sulphuric acid. The heating is effected first at 200 to 230 deg. C. and finally at 300 to 330 deg. C. The product is treated with water with slight agitation when the solution of the rare earths with the thorium compound in suspension is decanted from heavy residues and the thorium compound is filtered off. (Br. Pat. 151,854, LINDSAY LIGHT CO., Chicago; Dec. 15, 1920.)

Potassium Salts.—Leucite is ground to an impalpable powder preferably after first calcining alone or in presence of superheated steam, lime or magnesia, and the potash is then soluble in dilute acids such as acetic, formic, citric, oxalic and carbonic acids so that it may be used as a fertilizer. The potash may be extracted wholly or in part by treating in an autoclave with carbonic acid or with one of the organic acids mentioned at raised temperature and pressure. The product is leached to extract the potassium salt, and the residue, if it still contains potassium, may be used as a manure. (Br. Pat. 152,026; not yet accepted; G. A. BLANC and F. JOURDAN, both in Rome; Dec. 15, 1920.)

Paints for Leather.—A paint for leather consists of linseed oil, amber, sugar of lead, benzine and prepared paint. The linseed oil, amber and sugar of lead are heated together to 600 deg. F. and then allowed to cool. The thick paste thus formed is dissolved in benzine and mixed with paint, preferably also thinned with benzine. (Br. Pat. 151,853, J. RICHARD and A. DUBOIS, Montreal; Dec. 15, 1920.)

Testing Hardness.—Relates to the ball test by the Brinell method, and consists in the combination of a hardened steel ball, a striker for facing the ball against the material under test, and a standard member movably positioned between the ball and the striker, the holder for the ball being of a resilient character to permit of the removal or insertion of a ball. Within a sleeve or holder *a*, *b*, formed of two parts screwed together, is the striker *g*, normally forced downward by a spring *i* acting on a flange *h* so as to bear upon a rectangular bar *e* of uniform strength and hardness, that rests upon the ball *f* held in extensions *c* of the sleeve. When the complete gage is held with the ball resting upon the material under test, and the striker is struck with a hammer, impressions are made both in the standard and the material, and the relative dimensions of these determine the hardness. The extensions *c* of the sleeve are sufficiently resilient to admit of being forced open when it is required to replace a ball. In modifications, the necessary movement of the standard to present a new surface for each test may be obtained alternatively by the use of a rotatable standard. (Br. Pat. 152,000; not yet accepted; POLDIHÜTTE TIEGELGUSZTAHLFABRIK, Kladno, Czechoslovakia; Dec. 15, 1920.)

Anthranol.—Anthranol or gamma-hydroxy-anthracene is obtained by reducing anthraquinone. Instead of the usual reducing agents—such as zinc and acetic acid—it is proposed to use caustic alkali in the presence of a carbohydrate such as glucose, cane sugar, molasses, maltose or lactose. (Br. Pat. 151,707, A. G. PERKIN, Leeds; Dec. 15, 1920.)

Nitration of Oils.—The nitration of fatty, vegetable, animal or fish oils, or the fatty acids derived from such oils, is effected in the presence of an inert solvent, and the product either used as such or after separation of the solvent. According to the provisional specifications, the oil or fatty acid may be nitrated in the absence of a solvent. The oils specially suitable are tung oil, castor oil, lumbang oil, groundnut oil, cottonseed oil, soya bean oil, whale oil, linseed oil or herring oil; while as solvents, white petroleum spirit and the naphthene residue from the nitration of Borneo spirit are mentioned. The nitration is usually effected under agitation and using pure nitric acid with the application of heat, but dilute nitric acid may be employed and the reaction may take place under increased or reduced pressure or in the presence of an inert gas. During nitration ammonium nitrate, picric acid or nitrated benzene may be added; after nitration the excess of acid is neutralized by the addition of a nitratable solvent or of a base such as lime. Resin may be added before or after nitration, while pigments or filling materials may be added to the products, which may be employed in the manufacture of paints, varnishes, lacquers, cements, insulating compositions and rubber substitutes. (Br. Pat. 152,095, G. H. HOWSE, Birmingham; Dec. 15, 1920.)

Pyrogenic Reactions.—In carrying out organic reactions at high temperatures, the deposition of solid carbon on metallic parts of the apparatus is prevented by coating the metal with tin or a tin alloy. The tin layer also acts as a catalyst. The production of benzene and toluene from cresol by treatment with hydrogen at 800 deg. C. in an apparatus consisting of

tinned iron tubes is given by way of example. (Br. Pat. 152,960; not yet accepted; F. FISCHER, Mulheim on Ruhr, Germany, Jan. 12, 1921.)

Hydrogen From Electric and Blast Smelting Furnaces.—Hydrogen or mixtures of nitrogen and hydrogen are obtained by treating with steam and preferably in the presence of a catalyst the gases from electric and blast smelting furnaces, and subsequently eliminating the steam, carbon monoxide and carbon dioxide; hydrogen is obtained if the gases treated are those from electric smelting furnaces or from blast furnaces fed with oxygen; in other cases, a mixture of nitrogen and hydrogen is obtained, the relative proportions of the two constituents depending on whether the furnace is blown with air or air enriched with oxygen. The hydrogen obtained from electric furnace, etc., gases may be mixed with the poorer mixtures from blast-furnace gases, or with nitrogen; also, this poorer mixture may be mixed with hydrogen. The gases after reaction with steam are passed through water scrubbers to remove the excess of steam, and then treated with alkali or alkali earth substances or with water under pressure to remove carbon dioxide; traces of carbon monoxide and carbon dioxide are removed by caustic soda, copper salts, etc. When suitably purified, the gases may be used in the hydrogenation of fats, the synthesis of ammonia, as fuel for internal-combustion engines, and for welding. (Br. Pat. 152,975; not yet accepted; C. TONIOLO and OFFICINE ELETTRICHE DR. ROSSI, Legnano, Italy; Jan. 12, 1921.)

Ferrochromium.—Carbon-free ferrochromium is obtained by the thermo-aluminic reaction of a mixture of chrome iron ore, aluminum or other reducing metal, and oxides of iron, preferably roll scale. Oxides of other metals, such as cobalt, nickel, tungsten, molybdenum and vanadium, may be added to produce the corresponding alloys. (Br. Pat. 152,990. T. GOLDSCHMIDT AKT. GES., Essen, Germany; Jan. 12, 1921.)

Benzene.—In the recovery of benzene and its homologues by means of steam distillation from the acid sludge produced in the purification of benzol, the vapors carried over by the steam are subjected to the action of a jet or spray of ammonia in order to arrest the acid impurities. Steam is passed through the acid sludge

contained in the retort *B* and escapes along with the benzol vapor through an outlet pipe in the head of the retort, where the vapors are met by a jet of ammonia or a spray of ammonium carbonate solution introduced through the pipe *P*. The purified vapors then pass through a scrubber *Q*, in which any excess of ammonia is removed by means of dilute acid, to a condenser *U*, the benzol being finally separated into the vessel *E*. (Br. Pat. 152,054, G. STEPHENSON CROOK, Durham; Dec. 15, 1920.)

Current Events

in the Chemical and Metallurgical Industries

Aid Asked of Congress for Federal Power Commission

Successful operation by the Federal Power Commission is seriously hampered by lack of congressional appropriation for personnel and other needs and continuation even of the present staff will be difficult next year unless Congress comes to the rescue with more money. The commission requested an appropriation of \$482,000 for the year beginning July, 1921. The Appropriations Committee cut this to \$100,000, which was approved by the House, and this is the sum named in the sundry civil appropriations bill now pending in the Senate. There is little likelihood that it will be increased by the Senators, as it is felt that without authorization for increase in personnel the commission could not spend a larger sum effectively.

Representative Esch has introduced a bill (H.R. 15,126), now before the House select committee on water power, which is intended to correct these conditions by amendment of the Federal Power Commission Act in the following particulars:

1. Authorizing employment of personnel in the District of Columbia and elsewhere.
2. Permitting transfer to the Power Commission of employees of other Government departments without regard to the rule requiring three years' service before transfer, which now prevails.
3. Authorizing use of a portion of the appropriations for printing and binding, and purchase of books and periodicals.
4. Providing for reimbursement of other departments of the Government from the appropriations of the Power Commission for work done by these departments on request of the commission.

The Power Commission gets its staff now from the War and Agricultural Departments. As these have had their appropriations cut it will be more difficult to continue the present staff next year than it has been in the past. Therefore the need for the employment of a staff directly by the Power Commission is more urgent.

There are 160 applications, representing about 13,000,000 hp., now pending before the commission. This is five times the horsepower of all the applications handled by all of the Government departments in the twenty years preceding the establishment of the Power Commission. Means for handling this tremendous amount of business are not available.

Representative John J. Esch, of Wisconsin, is chairman of the House select committee on water power, and Representative Philip P. Campbell, of Kansas, is chairman of the House Rules Committee. The assistance of the latter is necessary since a special rule advancing the Esch bill must be brought in or the bill will fail for want of time at the present session.

Edgar F. Smith to Address New York Chemists

Invitations have been issued for a joint gathering of the New York sections of the American Electrochemical Society and the American Chemical Society, and the American sections of the Society of Chemical Industry and the Société de Chimie Industrielle to hear an address by Dr. Edgar F. Smith on "Research." The meeting will be held in Rumford Hall in the Chemists' Club on the evening of Feb. 11. Dr. Smith's prominent position among electrochemists and chemists in the United States warrants a large attendance, and his familiarity with his subject insures a profitable evening to those who attend.

Patent Bill Conference Delayed

Illness on the part of Senator Norris of Nebraska has delayed the conference on the Patent Office bill. Senator Norris is chairman of the Senate Committee on Patents. The other conferees have not felt justified in considering the bill during his absence.

Nitrogen Corporation Bill Believed Dead

Some of the strongest advocates of the bill authorizing the incorporation of the U. S. Fixed Nitrogen Corporation believe the measure has no chance to become a law at this session of Congress. The disinclination of Representative Kahn, chairman of the Committee on Military Affairs, to give the bill precedence before his committee is held mainly responsible for the delay which has overtaken the measure. Mr. Kahn is unwilling to report out the bill until each side of the controversy can be presented at a public hearing before his committee. To insure House action would require the intervention in behalf of the bill by the steering committee. It is believed that this committee is opposed to any effort to rush the bill through at this session.

Mining and Metallurgical Engineers Meet in New York

The annual meeting of the American Institute of Mining and Metallurgical Engineers will be held in New York Feb. 14 to 17, at Institute headquarters, Engineering Societies Building, 29 West 39th St. Hotel reservations for members and guests will be handled by Wilber Judson, 14 Wall St. Members of the Institute of Metals division are requested to make their reservations at the Hotel Seville, Madison Ave. and 29th St. The dinner and dance will be held Wednesday evening, Feb. 16, at the Waldorf-Astoria Hotel. Applications accompanied by remittance of \$5 per cover should be sent to Donald M. Liddell, Room 332, 2 Rector St. A smoker will be held Monday evening, Feb. 14, at Institute headquarters.

The program includes technical sessions on mining and metallurgy, non-ferrous metallurgy, non-metallic minerals, iron and steel, coal, industrial relations, petroleum and gas. There will also be a discussion of a proposed research on the heat-treatment of drill steel. Industrial films will be shown on the mining of asbestos and sulphur and the welfare work of the United States Steel Corporation. Luncheon will be served daily at Institute headquarters. Appropriate entertainment has been arranged for visiting ladies.

Meeting of the Louisiana Section A.C.S.

At the Jan. 21, 1921, meeting of the Louisiana Section of the American Chemical Society Dr. Charles E. Coates spoke on the use of kieselguhr as a sugar filtration medium, declaring that the solution of the filtration problems in sugar refinery work will eliminate many of the other present-day problems of that industry.

The microscopic examination of infusorial earth for filtering purposes was thought to give more information as to its action in filtration than a chemical analysis. Hydrated silica present in this material was thought to be responsible for cloudy filtration in some cases and this can be overcome by heating the infusorial earth to a dull red heat before using. The cost of infusorial earth per ton of sugar filtered can be cut by incinerating the earth, after filtering, to a dull red heat. Thus it may be used a number of times with equally good results. The carbon remaining in the incinerated earth has a slight bleaching power.

Another paper, by Mr. Slater of Bogalusa, La., on "Fuel Economy From the Standpoint of the Chemical Engineer," pointed out that the heat value of "black ash" in the paper pulp industry is very important and plans that are being worked out utilize it and reduce fuel costs.

The following officers of the section were elected for the ensuing year: Prof. H. Mosley, president; C. L. Clay, vice-president; W. R. Stryker, secretary and treasurer; F. W. Liepsner, member executive committee; Dr. Charles E. Coates, councilor.

January Meeting of T.A.P.P.I., Connecticut Valley Branch

The twenty-fourth meeting of the Connecticut Valley Branch of the Technical Association of the Pulp and Paper Industry was held on Jan. 18 in the social rooms of the American Writing Paper Co., Holyoke, Mass. R. B. Adams of Stowe & Woodard, Newton Upper Falls, Mass., spoke on "Rubber Rolls."

Mr. Adams said that the manufacture of rubber-covered rolls was a special branch of the rubber industry. He first reviewed the properties of rubber and told how the latex is obtained from the trees and converted into the raw material that is used by the factories. Most of the rubber today comes from the plantations of the Straits Settlements. The rubber, when it arrives at the factory, is broken, washed and run out into sheets. An interesting point brought out by the speaker was that in his mill a paper mill beating engine is used for washing the rubber.

Forsythe was the first to succeed in making a rubber-covered iron roll. He found that a very hard vulcanizing rubber could be united to the iron core. A thread of fourteen to the inch is cut on the iron body and the covering is then put on. The thread is used because it gives more surface for adhesion. The rolls are then wrapped in cloth and put into a steam boiler to be vulcanized, the time taken being ten to sixteen hours and the temperature about 260 to 270 deg. F. After vulcanization the wrapper is removed and the roll is then turned. The rubber next the iron body is so hard that high-speed steel tools cannot be used for turning, and diamonds are used instead.

The diseases of rubber rolls of interest to paper makers are corrugating, which is due to the stretching of the rubber and is curable, and checking, which is the breaking of the surface and is incurable.

The iron body should be cast vertically, like cannon, should be well balanced, have vent holes at each end and should be tively free of blow holes. Rubber can be vulcanized on cast iron best of all, next steel, and not very well on brass. Light, heat and dryness are enemies of rubber, while the opposites of these are preservatives.

Development of the British-American Nickel Co.

It is well known that the most important deposits of nickel known at the present time in America are in the Sudbury region of Ontario, Canada. During the early development of this district two men, M. J. O'Brien and R. C. Booth, became joint owners of a valuable deposit of nickel ore in this region. However, they lacked the necessary means for development, and an American, J. I. Holmes by name, determined to promote the property. He sailed to England to obtain capital and succeeded in getting both English and Norwegian financial men interested. The organization of the British-American Nickel Corporation resulted. Considerable development work and diamond drilling proved a greater tonnage of ore than was expected and a reduction plant was started when the war stopped the work. Dr. F. S. Pearson, one of the main American financial backers, was lost while en route to England on the Lusitania, together with all his papers and records. This further complicated and delayed the development of the nickel company.

At that time the affiliated Norwegians were operating a plant at Christiansand, making nickel by the Hybinette electrolytic process, which was sold to Germany at a very high price. Hearing of this traffic in nickel, the British Government on investigation determined to stop it. To this end it was necessary to pay the Norwegians a sum of money equivalent to that which they would have received from Germany, and also to aid the development of their Sudbury property. The British Government therefore advanced \$3,000,000 in return for 75 per cent of the capital stock of the company. It also agreed to take the output of the proposed reduction works in refined nickel for a period of ten years, at the prevailing London price in sterling. A smelter was hurriedly erected at Nickelton, Ont., and a refinery of about 5,000 tons nickel annual capacity at Duchene, near Ottawa, but the war was ended before

the plant was completed. Nickel was not shipped until about August, 1920.

In the meantime the demand for nickel has so lessened that the supply is more than sufficient for present needs. The bigger-producers—the International Nickel Co. and the Mond Nickel Co.—can more than supply the demand and have reduced their operating capacity to about 20 per cent of what it was during the war. These conditions, together with the fall of exchange, have probably made the production of nickel by the British-American Nickel Corporation a losing proposition. This situation has brought severe criticism on the British Government for its part in the transaction, which was but recently regarded as necessary as a war measure. A lively discussion is now under way among interested parties as to the propriety of the British Government canceling the amount it put into the industry as a necessary war expenditure, and turning the property over to private interests to work out its own salvation and succeed or fail according to its own merits.

Pending Petroleum Legislation

Several bills affecting the petroleum industry have been introduced in the legislatures indicated:

California: Every corporation, etc., in California owning or operating petroleum plants, or producing, refining, buying and selling or transporting crude petroleum is declared to be a public utility and subject to regulation by the Railroad Commission under the public utilities act. (Assembly Bills 12 and 27.)

Indiana: The use of a gage indicating the gravity of gasoline shall be required at all gasoline sales stations. (Bill 69.)

All gas and oil leases shall be void after failure for five years to operate or pay rentals and the Recorder's office shall provide for cancellation records.

New York: It shall be a penal offense for promoters of oil and mining corporations knowingly to make misrepresentations in an application to any stock exchange listing shares of such corporation. To advertise present or prospective earnings, value of property, etc., the president and board of directors must file with the state Comptroller detailed sworn statements of the facts to be advertised. (Bill 38.)

U. S. Senate: Whenever the President so proclaims it shall be unlawful to export petroleum or products to any country named in the proclamation. (Bill 4866.)

Niagara Water-Power Applications

The Federal Power Commission conducted hearings in Washington Jan. 24, 25 and 26 on the Niagara River applications made under the water-power act. The proceedings were simplified greatly by a ruling by the commission that no consideration would be given or discussion entertained on proposed use of water which might be made available if the treaty with Great Britain were amended. There was no disposition on the part of the commission to interfere with the existing arrangement whereby the Niagara Falls Power Co. uses 19,500 second-feet. The only one contesting the claim of the Niagara Falls Power Co. to that diversion was the city of Buffalo. It was brought to the attention of the commission, however, that the City Commission of Buffalo is divided on the question. John W. Van Allen, representing the Buffalo Chamber of Commerce, made strenuous objection to any additional allocation of power to the electrochemical and electrometallurgical companies at Niagara Falls. His argument was that these companies use a great amount of power and have few employees. Were the same amount of power made available in Buffalo and its diversified industries employment could be given to a much larger number of persons. The members of the Federal Power Commission made it very clear that they take no stock in such reasoning.

A.C.S. Advisory Committee to Meet Soon

A meeting in Washington in the near future of the American Chemical Society's advisory committee on chemical warfare matters has been requested by General A. A. Fries, head of the Chemical Warfare Service.

Meeting of the Chicago Section of the A.C.S.

The Chicago Section of the American Chemical Society met at the City Club on the evening of Jan. 1 with an interesting program prepared by the lady members and conducted under the leadership of Dr. Ethel M. Terry. The principal speaker of the evening was Dr. Paul Nicholas Leech, chief chemist of the American Medical Association, who spoke on "Home Remedies." It has been a long time since so interesting a paper has been delivered before this section, not only from the technical point of view but in outlining the work the American Medical Association has carried on in combating the makers of patent medicines and so-called shot-gun mixtures.

It was surprising to learn that Lydia Pinkham died in 1883, that Jess Willard was enabled to defeat Jack Moran and Jack Johnson through the use of Nuxated Iron, while Jack Dempsey in turn defeated Willard because he also took the same preparation, although evidently in greater quantities. Congressman Mason from the Chicago district also found that Nuxated Iron relieved him from that horribly tired feeling which one was so apt to acquire in Washington. Dr. Leech also proved to the satisfaction of the audience that such artists as Schumann-Heink, Julia Marlowe and Harrison Fisher, while exceedingly lucky in their artistic endeavors, are not necessarily intelligent as regards the chemical content and therapeutic value of patent medicines.

Meeting of Rochester Section, A.C.S.

The Rochester Section of the American Chemical Society on Monday evening, Jan. 24, listened to a lecture by Dr. John E. Teeple, treasurer of the American Chemical Society and consulting chemist and chemical engineer of New York City.

Dr. Teeple spoke on the subject "Some Problems in Handling Brines." He stated that about 70 per cent of the potash produced in this country during the last few years was obtained from the brines found in Nebraska, Utah and California.

The oldest and largest plant in the United States is at Searles Lake, owned and operated by the American Trona Co. This very unusual lake is located in San Bernardino County not very distant from Death Valley and Funeral Ridge. Its area is equivalent to about twelve square miles and its depth is between 60 and 70 ft. The lake is fed from underneath and the composition of the brine can be said never to vary. It is estimated that there must be about 12 million tons of potassium chloride in the brine and about 40 million tons of this same material in the salts. The reason that this potash has not been recovered before is because of the difficulty of separating it from the other salts present such as sodium chloride, sodium sulphate and borax.

The brine taken from the potash plant is obtained at about 50 ft. below the surface and its temperature is practically constant winter and summer. Of the numerous salts present in this brine only the potassium chloride and borax are valuable enough to be shipped, the freight on the sodium chloride and sodium sulphate being more than they are worth. The brine contains nearly 4.5 per cent of potassium chloride and about 65 per cent water. Various schemes for evaporating or getting rid of this large amount of water have been tried. At present triple effect vacuum pans are being used because they were in the original installation.

The most difficult chemical problem in handling this brine was to get rid of the sodium sulphate so that the potassium chloride would be left free. This was finally done by forming a double salt consisting of sodium chloride and sodium sulphate. The brine now contained borax with the potassium chloride, but this difficulty was overcome by cooling the brine rapidly so that the potassium chloride would be immediately precipitated and then the mother liquor poured off would later precipitate the borax. This method gives extremely pure borax and potassium chloride, the former ranging 99 per cent and the latter 92-99 per cent.

Another difficulty experienced was foaming in the vacuum pans during evaporation. It was finally thought to be due to organic matter in spite of the apparent lack of vegetation and animal life in this vicinity. So a study of the watershed

was made. The trouble was finally traced to minute quantities of an organic substance coming from the creosote bush which grows in that region. Certain alcohols and sulphonic acids will prevent the foaming. The efficiency of the plant is not at its highest, but work is constantly going on to improve it. The greatest costs are freight and fuel. If co-operation can be obtained from the oil producers and railroads, a large portion of the country's needs of potash can be supplied without even the protection of a tariff. It seems that this industry should be protected, however, for a few years hence Germany in her urgent need for money and goods will be sorely tempted to convert some of her supplies of potash into cash. Should this protection last about three years, it would enable most of the investigations and development work under way to be finished and thus the country would be on a firm foundation to produce a considerable quantity of its own. Should production drop off there would be little incentive to keep spending money on the problems confronting this youthful industry. The average consumption based on last year's prices is about \$60,000,000 and based on pre-war prices it would be about \$20,000,000. It would seem either figure would justify the encouragement of the growth of the potash industry in this country.

American Engineering Council Opens Office in Washington

The transfer of the activities of Engineering Council and Engineering Societies Service (Employment) Bureau was made on Jan. 1 to American Engineering Council. An office has been opened by American Engineering Council in the McLachlan Building, 10th and G Sts., Washington, D. C., with A. C. Oliphant as acting assistant secretary in charge. This office is available for the member societies of Engineering Council.

Engineering Societies Service Bureau is being maintained in the Engineering Societies Building, 29 W. 39th St., New York City, with Walter V. Brown in charge. Pending the development of a more permanent organization which may direct this very important activity of American Engineering Council, the secretaries of the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers and the American Institute of Electrical Engineers have been requested to act as a committee on management to conduct the Service Bureau until a permanent organization under American Engineering Council can be effected.

American Engineering Council to Meet in Syracuse

American Engineering Council will hold a two-day meeting in Syracuse, N. Y., Feb. 14 and 15. It is expected that Mr. Hoover will outline the new Council's plans for dealing with industrial relations, and particularly with unemployment. L. W. Wallace, who is assuming the duties of the Council's new committee on elimination of waste in industry, will discuss the subject of how to get America's idle men back to work and keep them at work. The Syracuse meeting will mark the beginning of a movement to organize engineers on a territorial basis, through the formation of State Engineering Councils under American Engineering Council.

Lower Silver Content in English Token Coins

During the high level of silver prices the bullion content of silver coins was worth more than their face value. Great quantities were melted and refined for export to the Orient both in Great Britain and the United States. New coins 0.500 instead of 0.925 fine are being introduced in England and the old silver pieces will be gradually withdrawn from circulation.

Dye Bill Compromise Rumored

A compromise has been effected between the friends and opponents of the dyestuffs bill, according to a rumor in circulation in Washington last week. Senator Curtis, the majority whip, expressed the opinion that the compromise has come too late to make possible the passage of the bill at this session.

Senate Resolution Asks for Fertilizer Report

Senator Fletcher of Florida has introduced a resolution calling upon the Department of Agriculture to advise as to "the amount of commercial potash, nitrogen and phosphoric acid available for fertilizer purposes, and the price of each of these articles, as compared with the prices for 1913." The resolution also asks for suggestions for relieving the situation in case the amount of any of these materials is insufficient or the price prohibitive. Senator Fletcher is anxious to have the department make a report similar to the one issued by it in 1916.

Book Reviews

CHEMISTRY AND CIVILIZATION. By *Allerton S. Cushman*, director, Institute of Industrial Research, Inc., Washington, D. C. 148 pages and index; illustrated. Boston: Richard G. Badger, 1920. Price \$2.50.

For the "tired business man" whose idea of chemistry is the study of substances which smell like asafetida and which probably explode if you look at them, this very entertaining book will prove both interesting and a revelation. The historical prologue and the short biographical sketches interspersed throughout the text add a most interesting touch to Dr. Cushman's story of the development of the science of chemistry and the marvelous achievements which it has made possible.

Nitrogen fixation, the Brownian movement, colloids and dispersoids, are all explained so that he who runs may read, but the author with a nice sense of values has given the reader only so much of the purely scientific side as is necessary to explain the commercial possibilities and accomplishments of chemical engineering. Alloy steels, dyes, explosives, artificial leather and many other products of everyday interest are bereft of their mystery and explained in the simplest possible language.

It is certain that after reading the book a millionaire clothing manufacturer or embryo bank president will bemoan the shortsightedness of his parents and wish that he had had the opportunity to study for a Ch.E. degree. If someone could place 10,000 of these books in the hands of as many college men studying for an A.B. degree there is no doubt that a big switch in courses would immediately take place.

IRVING FELLNER.

Personal

ROSCOE BRUNNER, chairman of Brunner, Mond & Co., Ltd. (England), has been appointed a director of the Allied Chemical & Dye Corp., New York.

FRANK K. CAMERON, who has been in charge of the development of chemical enterprises at the Western plants of the American Smelting & Refining Co., has severed his relations with that organization and has resumed practice as a consulting chemist and chemical engineer. He will retain an office in Salt Lake City as well as in New York.

MILO R. DAUGHTERS, chief chemist in charge of the research laboratory of the Dominion Cannery, Ltd., Brighton, Ont., delivered an address at the National Cannery Convention in Atlantic City, Jan. 20.

SIR ROBERT HADFIELD, inventor of manganese steel and leader of the British steel industry, has been awarded the John Fritz gold medal for notable scientific and industrial achievement.

Prof. A. S. LOEVENHART of the University of Wisconsin, who is now serving also as one of the consulting chemists of Chemical Warfare Service, is spending some time in Washington assisting in the physiological chemical research work of this service.

Dr. FILBERT ROTH, professor of forestry of the University of Wisconsin, spoke before the Detroit Engineers' Society, Friday evening, Jan. 21, on the forestry situation in the United States.

W. G. SWART, vice-president and general manager of the Mesabi Iron Co., Babbitt, Minn., was in New York last week on a business trip.

ALBERT M. WOLF, who for the past ten years has been associated with Condron Co., engineer, of Chicago, engaged in the design and supervision of construction of bridges and industrial buildings of all kinds, and **LAWRENCE M. HARPER**, who has been engaged in mechanical and structural work with the same company, have associated under the firm name of Wolf & Harper, engineers, to conduct a general engineering business, with offices at Room 1508, 7 West Madison St., Chicago. The new firm will specialize in the complete design of commercial and industrial buildings and structures, power plants, the valuation and appraisal of properties and the preparation of engineering reports.

Obituary

HERMAN GARLICH, a notable metallurgical engineer, died on Jan. 8 at his home in Brooklyn, N. Y., at the age of sixty-one.

ERNEST P. MAYER of Beaver Falls, Pa., died recently. Mr. Mayer was at the head of the Mayer China Co. and a pioneer member of the American Ceramic Society, having served as president of the society at Cleveland in 1902.

WILLIAM T. SEDGWICK of the Massachusetts Institute of Technology, an authority on biology and sanitation and for a time president of the American Health Association, dropped dead on the evening of Jan. 25 as he entered his home at 282 Berkley St., Boston, Mass., on returning from a conference at the Women's City Club. He had been a member of the faculty since 1883 and was the fourth prominent technology official to die suddenly in office, the others being three presidents, MacLaurie, Walker and Rogers. Prof. Sedgwick was born at West Hartford, Conn., in 1855, was graduated from Sheffield Scientific School in 1877, and taught for five years at Johns Hopkins.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Jan. 31, 1921.

Local trading in chemicals did not involve very large dimensions during the past week. The movement was irregular and presented chiefly small transactions for actual wants. Consuming demand was reported quiet in most directions. The only outstanding feature of the market was the pronounced advance in foreign exchange. This had a tendency to stiffen prices on some of the imported chemicals.

Quiet absorption of resale *caustic soda* took place at prices ranging from \$3.90@4 per 100 lb. Large dealers were very firm in their views at the outside figure. It is believed that second-hand stocks are not very large and that a few large orders would clear the shelves of all available spot supplies. Leading manufacturers are booking business with the consuming trade on contract at \$3.60 per 100 lb. f.o.b. works, basis 60 per cent. Moderate inquiries for export also reached the market. Small lots of *bichromate of soda* brought 8½c. a lb. and the market was reported quite steady at this level. Inquiries, while only of a small nature, reached the market in a somewhat freer volume. February shipments were held firm at prices ranging from 10@12c. per lb. Miscellaneous inquiries reached the market for *soda ash* and the tendency of prices appeared quite steady. Resale offerings were very light and

those who did offer any material were firm at \$2.10@2.25 per 100 lb. Odd lots in barrels were quoted from \$2.25@2.30. Producers have placed business for domestic consumption at \$1.72½ per 100 lb., basis 48 per cent f.o.b. works for single bags in carload lots for prompt and future shipments. The market in general showed a strong tendency to remain firm at this level.

Trading in *yellow prussiate of soda* was reported at 16½@17c. per lb. Some sellers continued to refuse any offers under 17½c. The market remained quite steady at the outside figure and there seemed to be a fair amount of inquiries on the market for prompt shipment. Concentrated *sodium sulphide*, 60-62 per cent, is obtainable at 3@5½c. per lb. Large resale offerings continued to reach the market in heavy volume through second hands, and these were sufficient to keep dealers' quotations considerably under those named by manufacturers. Iron free *alumina sulphate* is selling in the open market at prices ranging from 3@3½c. per lb. The commercial variety is quiet at 2¼@2½c. per lb. The demand for this commodity has not shown any activity of late and this has resulted in a lowering of prices in some directions in order to stimulate new business.

Producers continued to name 10c. per lb. for *chlorate of soda* f.o.b. works and reported the demand quiet. Moderate quantities of resale stocks are on the market and it is believed that firm business could meet lower figures. The principal movement at present is confined mostly to contract deliveries. Sales of second-hand stocks of *bleaching powder* in large drums were reported at 2½c. per lb. f.o.b. works for prompt shipment. Dealers stated that it was doubtful if much prime material could be purchased under 3c. per lb. on spot. Small drums were quoted from 2¾@3c. f.a.s., according to seller. Producers are holding the market at 3½c. per lb. works. Spot prices on *nitrite of soda* ranged from 6@7c. per lb., but in most quarters 6½c. was given as the regular market figure. It is reported that transactions involving a better tonnage were becoming somewhat freer and buyers were taking more interest than noted earlier in the month.

COAL-TAR PRODUCTS

The coal-tar products market showed an increased underlying strength throughout the week. Stocks seem to be in stronger hands and not only producers but dealers are firmer in their views on prices. There was a better inquiry and some improvement in the volume of sales, although it could not be said that holders were pushing business. Leading factors are viewing the market largely from a conservative standpoint and are waiting for the demand that is due to appear shortly. Textile mills in various sections reported better business in staple goods and a resumption in operation of from four to six days per week has been noticed.

Prices of *benzoic acid* were quoted around 70@75c. per lb. Business has been of a very narrow scope, with few inquiries resulting in actual sales. Some variation exists between makers of *H acid* as to price. In one quarter as low as \$1.25 per lb. was heard, while others quoted \$1.50 as the minimum figure. The demand has been very limited of late and since business has not been actually consummated it is impossible to determine any standard market figure. Quotations on *aniline oil* remained at former levels with producers still at wide variance as to price. Offerings were heard from 22@28c. per lb., according to sellers. A somewhat better inquiry has been noted during the week, but this has resulted in little actual business. Some trading in *aniline salt* was done during the week at prices around 27@29c. per lb. Large orders could probably be filled somewhat below these figures.

Benzidine base was held on a fairly steady basis at \$1@1.10 per lb. The sulphate variety remained firm at 80@90c. per lb. It is probable that actual business would bring out concessions under these prices. One of the most distressing features of the market was the sharp break in technical *beta naphthol*. Dealers reported moderate quantities available at 30c. per lb., with no response from domestic channels. The figure represented a reduction of 10c. per lb. and also the lowest price in recent years. Prices on

dimethylaniline ranged from 55@65c. per lb. The inside figure is being done by second hands and it is believed that manufacturers would be willing to meet it on a sufficiently large business. Tightening of spot stocks of *phenol* has forced prices up to 10c. per lb. in the open market. Although business has been of a very limited nature the lack of any large stocks with which to meet the demand has emphasized the effect of the light buying movement recently noted in the market.

WAXES

With primary markets holding steady and exchange rates generally firm, prices for *beeswax* were well maintained. A fair inquiry was noted in some directions for African crude and at the close of the week sellers' views ranged from 18@19c. per lb. On the refined grade prices held at 27@28c. With no apparent changes in figures at primary centers the market on *Carnauba wax* was quite steady. No. 3 North Country was available at 19@20c. per lb. with the chalky grade at 20@21c. The inquiry was along routine lines only. Offerings of Japan wax on the spot market were limited and the prices were maintained at 19@20c. per lb. Shipment quotations were firm at 17½c. per lb. With the market for crude oil easier and the demand for *paraffine wax* showing little improvement prices remained barely steady. Offerings of *scale wax* were fairly liberal and selling pressure was noted in some quarters. For the 124-126 crude there were offerings at 4½c. per lb., with intimations that slightly lower bids would be accepted. *Refined wax*, 133-135, was quotably unchanged at 9¼c. per lb.

The Baltimore Market

BALTIMORE, Jan. 28, 1921.

While the local market on fertilizer raw materials has not regained its normal activity some signs of life in the trade are to be noted. This is taking the form of numerous inquiries from out-of-town manufacturers and mixers for various kinds of materials. It is doubtful if active trading will be resumed for several weeks, although this depends upon the rapidity of shipments of mixed goods to the farmers. Local manufacturers have reported a movement of some goods during the past week.

It is generally felt that prices on many raw materials have reached their lowest levels, and as a consequence some manufacturers are beginning to anticipate requirements by taking advantage of the most attractive offerings.

The local situation is far from being normal, but a generally optimistic view of the future prevails in this market.

Acid Phosphate—Sales have been reported this week at \$15.50 per ton, basis 16 per cent A.P.A., bulk, run of pile. This price may be given as the nominal quotation, although distressed lots might be secured at a shade less.

Nitrate of Soda—Importers of this commodity are not actively quoting at this time and their attitude toward the market is bullish. There are a number of resale lots still available at prices around \$2.75 per 100 lb. ex-vessel or ex-store Atlantic ports.

Sulphate of Ammonia—The market remains unchanged on this commodity. It has been reported that contracts are being booked at \$3.75 per 100 lb., which was the price quoted in the last letter.

Potash—There has been rather active trading in foreign potash during the past two weeks, the majority of the sales made being at the following prices: \$1.50@1.60 per unit for muriate of potash; kainit and manure salts at \$1.40 per unit, all ex-vessel or ex-store Atlantic ports, foreign analysis and domestic weights. The nominal quotations are about 10c. per unit higher than sale prices given above. Nebraska potash continues to be held at a slight premium over the foreign goods.

Fish Scrap—Machine dried unground menhaden fish scrap may be had on this market today at \$3.50 per unit of ammonia and 10c. per unit B.P.L., ex-schooner Baltimore, in buyers' bags. Very little scrap is being absorbed at this price, because other organic ammoniates may be had at a somewhat lower figure.

The Iron and Steel Market

PITTSBURGH, Pa., Jan. 28, 1921.

In the actual condition of the iron and steel market no important change has occurred in the past week, and in the circumstances no important change could well occur. The market is practically stagnant, and is awaiting a completion of the readjustment through which business and industry generally are passing. Undoubtedly progress is being made in the general readjustment, but a long course is involved and many men who must contribute their part are tending to hang back.

OPERATIONS

Several independents whose plants have been idle for short periods have accumulated a little business and are resuming operations. At the moment the rate of independent steel production is increasing, but only to perhaps 30 per cent of capacity, and a trend in the other direction will doubtless follow.

The United States Steel Corporation, which has been operating at higher than 90 per cent for a couple of months and at a better rate than at any time between March and October, is probably now on the verge of a distinct decrease in operation, not because it has not a large volume of business on books but because its customers find they do not need material at as heavy a rate as was expected when orders were placed. Indeed, most of the business had been booked "for shipment at mill convenience," while now the buyer's convenience must also be consulted. However, only last Tuesday the Carnegie Steel Co. blew in an additional blast furnace, one of the Carrie group that had just been relined, making forty-eight Carnegie stacks in operation. Restriction in Steel Corporation operations has already begun in the Chicago district, and there is a slight decrease in the corporation's sheet mill operations, though more than 90 per cent of its sheet mills are still going.

PRICES

It is in line with all precedents that when the steel market is quiet there should be reports of price cutting, and in the past the outcome has usually shown that the reports exaggerated the conditions. The spreading of the reports is largely a psychological phenomenon. In the main prices are being held, but that means hardly anything, for there is little incentive to cut prices, so little competitive business being offered. On the other hand price cutting, even if extensive, would mean hardly anything, certainly nothing as to the eventual course of the steel market or the final level of prices. The main result of price cutting at this time would be to cause the Steel Corporation to lower its prices, readjusting prices on the large amount of business it has on books. Buying would not be stimulated to any extent, for the next real buying movement is going to be predicated upon steel prices much lower than can be named now, because costs have not yet been shaken down to the minimum possible.

The finished steel market as a whole can be quoted steady if not firm at the Industrial Board prices, as follows: Bars, 2.35c.; shapes, 2.45c.; plates, 2.65c.; hoops, 3.05c.; pipe, 57½ per cent basing discount; wire, 3.25c.; nails, \$3.25; blue annealed sheets, 3.55c.; black sheets, 4.35c.; galvanized sheets, 5.70c.; tin plate, \$7.

PIG IRON

Some offerings of foundry pig iron show that this grade can be bought from furnace at \$30 valley, against \$31.50 previously regarded as the quotable market. Bessemer and basic remain quotable at \$32 and \$30 respectively, with no inquiry whatever. No doubt lower prices could be done on a firm bid for a round tonnage. Possibly never in the history of the market has it been so stagnant or devoid of definite indication where actual values stand. A suggestion as to the uncertainty in pig iron generally is furnished by the fact that while Southern pig iron had been quoted rather generally as being at \$32 Birmingham, the Standard Sanitary Manufacturing Co. on an inquiry for 2,000 tons for first quarter delivery to its Louisville plant was able to do \$27.50 Birmingham.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

	Carlots	Less Carlots
Acetic anhydride.....lb.	—	\$0.55 - \$0.60
Acetone.....lb.	\$0.13 - \$0.13½	.13½ - .14
Acid, acetic, 28 per cent.....100 lbs.	3.00 - 3.25	3.50 - 3.75

Calcium carbide.....lb.	.04 - .04½	.04 - .05
Calcium chloride, fused, lump.....ton	27.00 - 29.00	30.00 - 32.00
Calcium chloride, granulated.....lb.	.01½ - .02	.02½ - .02½
Calcium hypochlorite (bleach'g powder).....lb.	.02½ - .02½	.03 - .03½
Calcium peroxide.....lb.	—	1.25 - 1.30
Calcium phosphate, monobasic.....lb.	—	.16 - .18
Camphor.....lb.	—	.85 - .90
Carbon bisulphide.....lb.	.08 - .08½	.09 - .09½
Carbon tetrachloride, drums.....lb.	.11 - .11½	.11½ - .12
Carbonyl chloride (phosgene).....lb.	—	.60 - .75
Caustic potash (see potassium hydroxide).....lb.	—	—
Caustic soda (see sodium hydroxide).....lb.	—	—
Chlorine, gas, liquid-cylinders (100 lb.).....lb.	.09 - .09½	.10 - .10½
Chloroform.....lb.	—	.43 - .50
Cobalt oxide.....lb.	—	3.70 - 3.80
Copper as (see iron sulphate).....lb.	—	—
Copper carbonate, green precipitate.....lb.	.22 - .22½	.24 - .25
Copper cyanide.....lb.	—	.50 - .60
Copper sulphate, crystals.....lb.	.06 - .06½	.06½ - .07
Cream of tartar (see potassium bitartrate).....lb.	—	—
Epsom salt (see magnesium sulphate).....lb.	—	—
Ethyl Acetate Com. 85%.....gal.	—	1.05 - 1.10
Ethyl Acetate pure (acetic ether 98% to 100%).....gal.	—	—
Formaldehyde, 40 per cent.....lb.	.18 - .18½	.18½ - .19
Fusel oil, ref.....gal.	—	3.50 - 3.60
Fusel oil, crude.....gal.	—	2.75 - 3.00
Glauber's salt (see sodium sulphate).....lb.	—	—
Glycerine, C. P. drums extra.....lb.	—	.20 - .21
Iodine, resublimed.....lb.	—	3.85 - 4.00
Iron oxide, red.....lb.	—	.10 - .20
Iron sulphate (copperas).....100 lb.	1.50 - 1.75	2.00 - 2.50
Lead acetate, normal.....lb.	—	.14 - .16
Lead arsenate (paste).....lb.	.11 - .12	.12½ - .13
Lead nitrate.....lb.	—	.15 - .20
Litharge.....lb.	.09 - .09½	.09½ - .10
Lithium carbonate.....lb.	—	1.50 - —
Magnesium carbonate, technical.....lb.	.10 - .11	.11½ - .12
Magnesium sulphate, U. S. P.....100 lb.	2.50 - 3.00	—
Magnesium sulphate, commercial.....100 lb.	—	1.50 - 1.75
Methanol, 95%.....gal.	—	1.30 - 1.40
Methanol, pure.....gal.	—	1.50 - 1.70
Nickel salt, double.....lb.	—	.12 - .12½
Nickel salt, single.....lb.	—	.13 - .13½
Phosgene (see carbonyl chloride).....lb.	—	—
Phosphorus, red.....lb.	.45 - .46	.47 - .50
Phosphorus, yellow.....lb.	—	.35 - .37
Potassium bichromate.....lb.	.14½ - .14½	.15 - .15½

		Carlots	Less Carlots

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	\$1.10 - \$1.15
Alpha-naphthol, refined	lb.	1.45 - 1.50
Alpha-naphthylamine	lb.	.38 - .40
Aniline oil, drums extra	lb.	.22 - .28
Aniline salts	lb.	.27 - .30
Anthracene, 80% in drums (100 lb.)	lb.	.85 - 1.00
Benzaldehyde (f.f.c.)	lb.	2.00 - 2.10
Benzidine, base	lb.	1.00 - 1.10
Benzidine sulphate	lb.	.80 - .90
Benzoic acid, U.S.P.	lb.	.70 - .75
Benzoate of soda, U.S.P.	lb.	.75 - .85
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 - .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 - .32
Benzyl chloride, 95-97%, refined	lb.	.30 - .35
Benzyl chloride, tech.	lb.	.25 - .30
Beta-naphthol benzoate	lb.	3.50 - 4.00
Beta-naphthol, sublimed	lb.	.75 - .80
Beta-naphthol, tech	lb.	.30 - .35
Beta-naphthylamine, sublimed	lb.	2.25 - 2.40
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 - .18
Ortho-cresol, in drums (100 lb.)	lb.	.23 - .25
Cresylic acid, 97-99%, straw color, in drums	gal.	.95 - 1.00
Cresylic acid, 95-97%, dark, in drums	gal.	.90 - .95
Cresylic acid, 50%, first quality, drums	gal.	.65 - .75
Dichlorbenzene	lb.	.06 - .09
Diethylaniline	lb.	1.25 - 1.30
Dimethylaniline	lb.	.55 - .65
Dinitrobenzene	lb.	.30 - .32
Dinitrochlorbenzene	lb.	.25 - .30
Dinitronaphthalene	lb.	.33 - .35
Dinitrophenol	lb.	.40 - .45
Dinitrotoluene	lb.	.25 - .30
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 - .40
Diphenylamine	lb.	.60 - .70
H-acid	lb.	1.30 - 1.50
Meta-phenylenediamine	lb.	1.25 - 1.30
Monochlorbenzene	lb.	.14 - .16
Monoethylaniline	lb.	1.75 - 2.25
Naphthalene crushed, in bbls. (250 lb.)	lb.	.08 - .08½
Naphthalene, flake	lb.	.08 - .08½
Naphthalene, balls	lb.	.09 - .09½
Naphthionic acid, crude	lb.	.70 - .75
Nitrobenzene	lb.	.12 - .15
Nitro-naphthalene	lb.	.35 - .40
Nitro-toluene	lb.	.18 - .25
Ortho-amidophenol	lb.	3.20 - 3.75
Ortho-dichlor-benzene	lb.	.15 - .20
Ortho-nitro-phenol	lb.	.75 - .80
Ortho-nitro-toluene	lb.	.20 - .28
Ortho-toluidine	lb.	.25 - .30
Para-amidophenol, base	lb.	1.90 - 2.00
Para-amidophenol, HCl	lb.	2.10 - 2.20

Para-dichlorbenzene	lb.	.15 - .25
Paranitroaniline	lb.	.90 - .95
Para-nitrotoluene	lb.	.95 - 1.10
Para-phenylenediamine	lb.	1.80 - 2.20
Para-toluidine	lb.	1.30 - 1.60
Phthalic anhydride	lb.	.55 - .60
Phenol, U. S. P., drums (dest.), (240 lb.)	lb.	.10 - .12
Pyridine	gal.	2.00 - 3.50
Resorcinol, technical	lb.	2.00 - 2.25
Resorcinol, pure	lb.	3.60 - 3.80
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.25 - .28
Salicylic acid, U. S. P.	lb.	.29 - .35
Salol	lb.	.85 - .95
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.28 - .32
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.16 - .18
Sulphanilic acid, crude	lb.	.30 - .35
Tolidine	lb.	1.40 - 1.60
Toluidine, mixed	lb.	.40 - .45
Toluene, in tank cars	gal.	.30 - .32
Toluene, in drums	gal.	.33 - .35
Xylidines, drums, 100 gal.	lb.	.45 - .50
Xylene, pure, in drums	gal.	.42 - .45
Xylene, pure, in tank cars	gal.	.45 - . . .
Xylene, commercial, in drums, 100 gal.	gal.	.33 - .35
Xylene, commercial, in tank cars	gal.	.30 - . . .

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark	lb.	\$0.24 - \$0.26
Beeswax, refined, light	lb.	.27 - .28
Beeswax, white pure	lb.	.40 - .45
Carnauba, No. 1	lb.	.75 - .80
Carnauba, No. 2, North Country	lb.	.35 - .40
Carnauba, No. 3, North Country	lb.	.19 - .20
Japan	lb.	.19 - .20
Montan, crude	lb.	.07 - .08
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.05 - .05½
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.04½ - .05½
Paraffine waxes, refined, 118-120 m.p.	lb.	.06½ - .06¾
Paraffine waxes, refined, 125 m.p.	lb.	.07½ - .07¾
Paraffine waxes, refined, 128-130 m.p.	lb.	.07¾ - .08
Paraffine waxes, refined, 133-135 m.p.	lb.	.09½ - .09¾
Paraffine waxes, refined, 135-137 m.p.	lb.	.10 - .11
Stearic acid, single pressed	lb.	.13½ - .13¾
Stearic acid, double pressed	lb.	.13¾ - .14
Stearic acid, triple pressed	lb.	.14¼ - .14½

Flotation Oils

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr. 0.930-0.940	gal.	\$1.70
Pine oil, pure, dest. dist.	gal.	1.60
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.	.48
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.	.75
Pine tar, ref., thin, sp.gr. 1.080-1.960	gal.	.36
Turpentine, crude, sp. gr. 0.900-0.970	gal.	1.20
Hardwood oil, f.o.b. Mich., sp.gr. 0.960-0.990	gal.	.37
Pine wood creosote, ref.	gal.	.55

Naval Stores

The following prices are f.o.b. New York for carload lots.

Rosin B-D, bbl.	280 lb.	\$8.75 - . . .
Rosin E-I	280 lb.	8.75 - . . .
Rosin K-N	280 lb.	8.75 - . . .
Rosin W. G.-W. W.	280 lb.	9.00 - . . .
Wood rosin, bbl.	280 lb.	9.00 - . . .
Spirits of turpentine	gal.	.72 - . . .
Wood turpentine steam dist.	gal.	.68 - . . .
Wood turpentine, dest. dist.	gal.	.67 - . . .
Pine tar pitch, bbl.	200 lb.	. . . - 8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	. . . - 15.00
Retort tar, bbl.	500 lb.	15.00 - 15.50
Rosin oil, first run	gal.	.52 - . . .
Rosin oil, second run	gal.	.54 - . . .
Rosin oil, third run	gal.	.62 - . . .

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	\$0.41
70-72 deg., steel bbls. (85 lb.)	gal.	.39
68-70 deg., steel bbls. (85 lb.)	gal.	.38
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.30

Crude Rubber

Para-Upriver fine	lb.	\$0.18½ - \$0.19
Upriver coarse	lb.	.14 - .14½
Upriver caucho ball	lb.	.14½ - .14¾
Plantation—First latex crepe	lb.	.20 - . . .
Ribbed smoked sheets	lb.	.19½ - . . .
Brown crepe, thin, clean	lb.	.18 - . . .
Amber crepe No. 1	lb.	.20 - . . .

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	\$0.09½ - \$0.10
Castor oil, AA, in bbls.	lb.	.11 - .11½
China wood oil, in bbls. (f.o.b. Pac. coast)	lb.	.08½ - .08¾
Cocanut oil, Ceylon grade, in bbls.	lb.	.12½ - .13
Cocanut oil, Cochin grade, in bbls.	lb.	.12½ - .13
Cor oil, crude, in bbls.	lb.	.08½ - .09
Cottonseed oil, crude (f. o. b. mill)	lb.	.06 - .06½
Cottonseed oil, summer yellow	lb.	.08½ - .09
Cottonseed oil, winter yellow	lb.	.09 - .09½
Linseed oil, raw, car lots (domestic)	gal.	.73 - .74
Linseed oil, raw, tank cars (domestic)	gal.	.66 - .67
Linseed oil, boiled, car lots (domestic)	gal.	.75 - .76

Olive oil, commercial.....	gal	\$2 25	\$2 40

*Add 10c per 100 lb. for trucking to Jersey City and 15c for delivery in New York and Brooklyn.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation California

LOS ANGELES—The Standard Film Laboratories, Seward St., has awarded the contract for the construction of a 2-story, 75x120-ft. film laboratory to Meyer & Holler, Collender Bldg., about \$125,000. Company plans to install \$50,000 worth of laboratory equipment.

TORRANCE—The Western Glass Co., 939 East 1st St., Los Angeles, plans to construct a plant here. Estimated cost, \$50,000.

Colorado

FORT COLLINS—The State Agricultural College is having plans prepared for the construction of a 2-story, 40x70-ft. women's club and chemistry building. Estimated cost, \$100,000. E. Groves, Foster Bldg., Denver, archt.

Florida

WEST PALM BEACH—K. Riddle, city mgr., is having plans prepared for laying main lines, laterals and installing septic disposal tank, etc. Estimated cost, \$100,000.

Illinois

ALTON—The Consolidated Chemical Products Co. plans to build a muriatic acid plant. J. W. Brandel, mgr.

Iowa

GILMAN—The Bd. Educ. is having plans prepared for the construction of a 3-story, 60x100-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$120,000. Keffer & Jones, 204 Masonic Temple, Des Moines, archts.

Kansas

PITTSBURG—The Atlas Powder Co. will build five 1-story, 25x55-ft. powder houses near here. Cost, about \$18,000.

Massachusetts

WORCESTER—R. F. Rob Power Co., Albany St., plans to rebuild its foundry building recently destroyed by fire. Estimated cost, \$50,000.

Michigan

DETROIT—Bd. Educ. has awarded the contract for the construction of a 3- and 7-story high school addition on Cass and Second Aves. A gas engine laboratory will be installed in same.

Minnesota

BEMIDJI—The Bd. Educ. is having plans prepared for the construction of a 2-story, 145x270-ft. high school on Main St. A chemical laboratory will be installed in same. Estimated cost, \$400,000. R. O. Bagley, Supt. E. F. Bromball, 707 Alworth Bldg., Duluth, archt. and engr.

LUVERNE—Bd. Educ. will receive bids until Feb. 17 for the construction of a 3-story, 68x120-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$300,000. F. A. Leicher, secy. Tyrie & Chapman, 1206 Second Ave., S., Minneapolis, archts.

MINNEAPOLIS—The Bd. Educ. will receive bids until Feb. 15 for the construction of a 4-story, 200x300-ft. high school on Monroe St. and 20th Ave., N. A chemical laboratory will be installed in same. Estimated cost, \$800,000. C. F. Womarth, City Hall, business supt.; E. H. Enger, 305 City Hall, archt. Noted Oct. 27.

New Jersey

DOVER—Jersey City plans to build main sewer and disposal plant for protection of Jersey City water pipe line here. About \$2,000,000.

TRENTON—The Puritan Rubber Co., Perrine Ave., plans to construct a 2-story,

60x80-ft. addition to take the place of one which was recently destroyed by fire.

WHARTON—Borough of Wharton will soon award the contract for construction of filtration plant and reservoir and laying 8 miles of pipe. Estimated cost, \$400,000. A. Potter, 50 Church St., New York City, engr.

North Dakota

KENMARE—City plans to construct septic tank, sludge bed and repair sewers. E. J. Thomas, Minot, engr.

Ohio

ALLIANCE—The city plans to vote on \$375,000 bond issue to construct a municipal artificial gas plant.

CLEVELAND—The Premier Refining Co., 1187 West 11th St., has awarded the contract for alterations to its factory on East 65th St. and Harvard Ave. Estimated cost, \$35,000. Noted Dec. 15.

PROSPECT—Bd. Educ. will receive bids until Feb. 8 for the construction of a 2-story high school. A chemical laboratory will be installed in same. About \$125,000. O. D. Howard, 8 East Broad St., archt.

Pennsylvania

DANVILLE—The Bd. of Educ. had plans prepared for the construction of a 3-story, 80x160-ft. high school. Estimated cost, \$200,000. A chemical laboratory will be installed in same. Richter & Lee, 32 South 17th St., Philadelphia, archts.

South Dakota

RAPID CITY—The State Senate, Pierre, has passed a bill appropriating \$2,000,000 for the purchase of a site and constructing a cement plant.

WAVERLY—The Bd. of Educ. will soon award the contract for the construction of 2-story, 80x109-ft. consolidated school. A chemical laboratory will be installed in same. Estimated cost, \$100,000. K. T. Snyder, 738 Plymouth Bldg., Minneapolis, Minn., archt. Noted Dec. 29.

Texas

LOCKHART—School Bd. is having plans prepared for the construction of a 2-story high school. A chemical laboratory will be installed in same. Estimated cost, \$200,000.

WEATHERFORD—School Bd. is having plans prepared for the construction of a 2-story high school. A chemical laboratory will be installed in same. Estimated cost, \$200,000.

Wisconsin

TAYCHEEDAH—The State Bd. of Control, Madison, rejected all bids for water softeners in connection with the power plant at the Wisconsin Industrial Home for Women. Bids will readvertised.

Ontario

CHATHAM—City plans to construct a filtered water basin and reservoir about 250,000 imperial gal. capacity. Estimated cost, \$50,000. C. H. R. Fuller, Chatham, engr.

OSHAWA—Town plans to build sanitary and storm sewers and Imhoff sewage disposal plant. About \$350,000. M. Shupe, town engr., Gore, Nasmith & Storrie, Toronto, consulting engr.

PETERBOROUGH—City receives bids after Feb. 1 for the construction of a rapid sand filtration plant, rein.-con. with a brick building over filters, coagulating basins, alum tanks, chlorinating apparatus, etc. Estimated cost, \$350,000. S. H. Parsons, City Hall, engr. Noted Jan. 19.

Quebec

MONTREAL—The E. F. Phillips Electrical Works, Ltd., De Gayre St., will receive bids about Feb. 7 for the construction of a copper rod rolling mill to have a capacity of 100 tons daily. Estimated cost, \$175,000.

British Columbia

PORT MELLON—The Western Canada Pulp & Paper Co. plans to construct a plant to have capacity of 40 tons of pulp daily. H. H. Helin, mgr.

Manufacturers' Catalogs

DWIGHT P. ROBINSON & Co., Inc., New York City, has issued two new booklets. "Work Done" gives in 192 pages illustrations and short descriptions of the work that has been done by this company. The other booklet, entitled "Clients," gives its list of clients according to industries.

PROCTOR & SCHWARTZ, Inc., Philadelphia, Pa., formerly known as the Philadelphia Textile Machinery Co., has issued an attractive catalog on "Proctor Dryers for Pigments, White Lead, Lithopone, Chemicals." Many interesting illustrations are given of the different types of drying machines, together with descriptions.

ELECTRIC FURNACE CONSTRUCTION Co., Philadelphia, Pa., has published a pamphlet on "Heat Treating and Annealing Furnaces," by Frank W. Brooke and George P. Mills, which discusses electric vs. combustion furnaces.

THE CLEVELAND AIR ENGINEERING Co., Cleveland, O., is issuing an 8-page booklet on "The Cleveland Automatic Reclaiming Separators," which are described and illustrated.

AUSTIN MACHINERY CORP., Chicago, Ill., is issuing a series of attractive art letterheads of an industrial character for following up inquiries on special types of mechanical equipment.

THE BARRETT Co., New York City, announces a new catalog entitled "Flotation Oils and Reagents."

THE NORTON Co., Worcester, Mass., calls attention to a new catalog on "Steadyrests, Form Grinding, Grinding of Plane Surfaces." Under "Steadyrests" is given the story of the development and a study of correct workshoes and the effect of steadyrests on production and suggestions for their use; under "Form Grinding" the evolution and the principles of the wide face wheel in grinding as related to form grinding, application of wide face wheel to grinding of irregular shapes, description of attachments and general suggestions; under "Grinding of Plane Surfaces" is given the types of machines, selection of wheels, accuracy possible, methods of handling work, and kinds of materials ground.

THE KEWAUNEE MFG. Co., Kewaunee, Wis., has just received from the press Catalog 14, on "Kewaunee Laboratory Furniture for Educational Institutions, Commercial Laboratories, Industrial Plants and Hospitals."

THE WRIGHT-AUSTIN Co., Detroit, Mich., announces three new publications on its products. These books deal with Austin separators, steamtraps, strainers and boiler trimmings and contain new data and useful information of interest to engineers and steam users.

ROSS HEATER & MFG. Co., Inc., Buffalo, N. Y., calls attention to Catalog "F," which illustrates and describes the various types of heaters, condensers, expansion joints, coolers and airjet pumps. Many illustrations are included.

THE SCOVILL MANUFACTURING Co., Waterbury, Conn., has issued a four-page folder on "Scovill Seamless Tubing." Another new publication is entitled "Getting Down to Brass Facts."

THE DEISTER CONCENTRATOR Co., Fort Wayne, Ind., has issued bulletin No. 6, which is a four-page folder on the No. 7 Deister-Overstrom Diagonal Deck Coal Washing Table.

THE MILWAUKEE ELECTRIC CRANE & MFG. Co., Milwaukee, Wis., has just issued a 48-page catalog illustrative and descriptive of its complete line of cranes. Information, which is the result of twenty-five years of active experience in the designing and building of hoisting machinery for shops, foundries, steel plants and other establishments, is incorporated in this book. A section of the book is devoted to the horizontal drilling and boring machine which is suited for operating, at one setting, on pieces too long or bulky for the usual type of machine. Copies may be had on request.

CROUSE-HINDS Co., Syracuse, N. Y., has published Bull. 304-A, on Crouse-Hinds Imperial Floodlight Projectors and Imperial Reflectors, which contain listings of projectors and reflectors developed since the publication of Bull. 304, which is still effective.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its annual meeting Feb. 21 to 24 at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN ENGINEERING COUNCIL will meet at Syracuse, N. Y., Feb. 14 and 15.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its spring meeting June 20 to 24 at Detroit. Industrial excursions will be made to Ann Arbor, Saginaw, Midland and Bay City.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting Feb. 14 to 17 in New York City.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

CHAMBER OF COMMERCE OF THE UNITED STATES will hold its ninth annual meeting in Atlantic City April 27, 28 and 29.

COMMON BRICK MANUFACTURERS' ASSOCIATION OF AMERICA is holding its annual meeting at the Hotel Pennsylvania, New York City, Jan. 31 to Feb. 4.

NATIONAL PETROLEUM CONGRESS will meet at the Hotel Baltimore, Kansas City, Mo., March 22 to 25.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

THE SEVENTH EXPOSITION OF CHEMICAL INDUSTRIES will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: Feb. 11, American Electrochemical Society, joint meeting with Society of Chemical Industry, American Chemical Society and Société de Chimie Industrielle; March 11, American Chemical Society; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society, Nichols Medal award; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Industrial Notes

THE NATIONAL ANILINE Co. is sending sample sets of American-made dyes, comprising seventy-one dyes, to all the prominent colleges and universities in the United States.

THE ENGINEERING BUSINESS EXCHANGE, established some time ago by Charles Whiting Baker for the purchase and sale of engineering and technical business properties, announces the opening of a Pacific Coast branch with James T. Whittlesey as manager, with offices in the Claus Spreckels Bldg., San Francisco, Cal.

THE GOULDS MANUFACTURING Co. of Seneca Falls, N. Y., manufacturer of Goulds pumps, announces the appointment of Edward S. Jenison as acting general sales manager to succeed W. E. Dickey, who retired from business on Jan. 1. For the past five years Mr. Jenison had been manager of the Philadelphia office.

THE B. F. GOODRICH RUBBER Co., pioneer manufacturer of mechanical rubber goods and other rubber products, is now entering upon the second half of a century of progress. The first half of the century was completed Dec. 31, the company having been incorporated Dec. 31, 1870, by Dr. Benjamin Franklin Goodrich. Dr. Goodrich, who was a physician by profession, entered the rubber business as result of having acquired a rubber factory at Hastings-on-the-Hudson in a real estate deal. Seeking financial help he was attracted to Akron, where a group of progressive citizens promised to back him. He began manufacturing in a small two-story brick building with a force of twenty-five employees. This small factory has grown until today it comprises sixty-three giant buildings covering 110 acres of ground.

It is related that one time when Dr. Goodrich was trying to find a market for his goods he tried to sell rubber hose to the fire department of Cincinnati, which still used leather hose. The firemen scoffed at Dr. Goodrich's contention that rubber hose would be much superior to the leather, and refused to buy. It wasn't many years, however, before Dr. Goodrich had the laugh on them, for rubber fire hose soon came in universal use. After starting with the manufacture of hose Goodrich added article after article to its line of manufactured goods until today approximately 30,000 different rubber products are made, filling an almost infinite variety of needs. They can be classified into five general divisions, each ramify into numerous subdivisions: Mechanical goods, rubber footwear, druggists' sundries, hard rubber products, and tires—both pneumatic and solid. The manufacture of automobile tires followed naturally from Goodrich's early experiments in perfecting rubber shod wheels. Solid rubber tires for carriages were made first. Then came the pneumatic tires for bicycles, made in large numbers when the "bike craze" swept over the country. Auto tires came next, the same fundamental principles being used in their construction as for bicycle tires. With the universal use of the motor car today it is difficult to realize that so short a time ago as 1896 Goodrich produced the first American clincher type tires for automobiles. The Goodrich company commemorated the golden anniversary by publishing an attractive 48-page book called "The Golden Year of Goodrich," telling of the romance of the rubber industry, its history, and of what great importance it has been in the progress and development of the world. The book was written by Wilbur D. Nesbit and illustrated by W. T. Benda, the famous Polish-American painter.

THE WEIR FOUNDRY, at the northwest corner of Wallace St. and 24th Pl., Chicago, has been sold by Robert Weir to William McIlvaine, for a consideration of \$95,000.

D. J. LEWIS, JR., New York sales agent for the Cresson-Morris Co. and the Kestner Evaporator Co., Philadelphia, Pa., announces the removal of his offices from 277 Broadway to the Woolworth Bldg.

THE PORTLAND VEGETABLE OIL MILLING Co., Portland, Ore., has recently been incorporated to import and refine copra, and oils such as those of the peanut and soya bean. Large quantities of vegetable oil are being brought to Portland by steamers operating in the transpacific trade.

WHITING FOUNDRY EQUIPMENT Co., Harvey, Ill., announces that it has changed its name to Whiting Corporation, increasing its authorized capital stock from \$700,000 to \$3,000,000. The Whiting Corporation remains under the same management and will continue the manufacture of cranes, foundry equipment and railway specialties as heretofore.

CHICAGO PNEUMATIC TOOL Co. announces the appointment Jan. 1, 1921, of R. F. Eisler as assistant to the vice-president, with headquarters in the company's new office building at 6 East 44th St., New York. W. C. Straub, formerly district manager of the New Orleans branch, has been appointed district manager of the Pittsburgh branch to succeed Mr. Eisler, and Ross Wyeth, formerly attached to the Pittsburgh branch, has been appointed district manager of the New Orleans branch to succeed Mr. Straub.

THE CUTLER-HAMMER MFG. Co., Milwaukee, Wis., has secured new offices in the Railway Exchange Bldg., St. Louis, which is a branch of the Chicago district office. Harold Phillips, formerly of the engineering department of Chicago and later office manager of the Chicago office, will be in charge of the new St. Louis branch.

GARRED-CAVERS CORP., New York, announces that arrangements have been made with it by the Union Minière de Haut-Katanga for the use of its process, whereby pulverized coal is used to replace coke in blast furnaces. The Union Minière du Haut-Katanga has placed orders for a 42-in. Fuller mill and a Fuller-Kenyon pump for the coal-preparation plant which will be used in connection with the above process at its copper smelter in the Belgian Congo. Licenses were secured from the Garred-Cavers Corp. some time ago by the Cerro de Pasco Copper Corp., Peru, the International Nickel Co. and the Tennessee Copper Co., for the use of this process at their various smelters.

THE HALLIDIE MACHINERY Co., L. C. Smith Bldg., Seattle, Wash., has been appointed representative of the Conveyors Corporation of America, Chicago, formerly the American Steam Conveyor Corporation. It will handle the sale of the American Steam Conveyor and American Trolley Carrier in the states of Washington and Oregon.

PARRY, LEON & HAYHOE, LTD., Johannesburg, South Africa, announces the discovery of a high-grade chromium ore in southern Rhodesia. The property is being developed by the United Chrome Prospecting Syndicate, Ltd., and is now yielding from 800 to 1,000 tons per week. A sample of 500 tons shipped to Liverpool showed the following analysis:

	Dry Ore, Per Cent
Oxide of chromium.....	55.40
Protoxide of iron.....	16.39
Peroxide of iron.....	1.78
Alumina.....	9.40
Lime.....	1.50
Magnesia.....	12.72
Oxide of manganese.....	.10
Silica.....	1.54
Sulphuric acid.....	.17
Combined water, etc.....	.97
	99.97
Moisture in ore as received.....	0.88

Other samples taken from the same property contained 56.1 per cent oxide of chromium.

THE AUSTIN MACHINERY CORPORATION of Chicago, manufacturer of earth-working, concrete-mixing and material-handling machinery, has purchased the large plant of the Fairmont Machine Co., Fairmont, W. Va. This plant will continue to make a total line of machinery, besides contributing to the manufacture and distribution of the complete line of the Austin Corporation.

THE NORTHWESTERN CHARCOAL Co., of Olean, N. Y., has acquired ground for the erection of a plant near the Forest Products Chemical Co., at Memphis, Tenn. Charcoal from the Forest Products Chemical Co.'s ovens will be used at the new plant in the preparation of material for case-hardening and steel-treating compounds as well as for poultry and stock feed. Estimated investment will amount to around \$100,000. R. M. Hancock, of Cadillac, Mich., will be in charge of the new plant, which it is expected will be in operation about April 1.

THE GALION IRON WORKS & MANUFACTURING Co., of Galion, O., has established a distributing warehouse at 477 South Front St., Memphis, Tenn., in charge of R. M. Hammond. The new sales organization will handle a full line of road-building machinery, contractors' equipment and culvert pipe.

THE SOUTHERN CHEMICAL & MANUFACTURING Co., INC., has located at 17 South Cooper Ave., Memphis, Tenn., and will engage in the manufacture of liquid soaps, disinfectants, cleaners and polishes of various kinds. It is incorporated under the laws of Tennessee, with E. A. Hall, president and general manager; H. F. Reed, secretary-treasurer.

THE SEK MANUFACTURING Co., of Chicago, has established a branch agency at Memphis, Tenn., for the sale of preservative and waterproof compound for leather, cotton, shoes, automobile tops, etc. The branch office is in charge of Al Finberg.

THE METALS REFINING Co. has purchased twenty acres of land at Hammond, Ind., for the erection of a plant to produce lead for battery plates.

S. MORTIMER WARD, JR., GORHAM CROSBY and DYER SMITH announce that on Jan. 1, 1921, they became associated in the practice of patent and trade-mark law under the firm name of Ward, Crosby & Smith, with offices in the Woolworth Bldg., 233 Broadway, New York City.

THE YARNALL-WARING Co., Philadelphia, Pa., announces that H. J. Moyer, who has jointly represented that company and the Nelson Valve Co. in the Chicago territory, has severed his connection with the latter concern and will henceforth represent the Yarnall-Waring Co. exclusively in that field as district manager, with offices at 58 West Washington St.

THE SUREWAY CHEMICAL Co. has recently been organized in St. Louis, Mo., to deal in scale solvents. The company is incorporated for \$10,000. Further information may be had from Hans Fonseca, 1525 Bremen Ave., St. Louis, Mo.

WILSON-MAEULEN Co., New York City, manufacturer of pyrometers, announces that William Printz, sales engineer, has assumed charge of the New York territory. He has been actively associated with the sale and installation of pyrometers throughout the Middle West for the past five years. Mr. Printz will have his headquarters at the main office and works, 383 Concord Ave., New York City.

SHARPSVILLE BOILER WORKS Co., Sharpsville, Pa., announces the appointment of F. M. Patterson, 2 Rector St., New York City, as Eastern sales manager, succeeding R. C. Luty.

International Migration of Technical Men And the Diffusion of Manufacturing Secrets

INTERPLANT migration of technical men and diffusion of manufacturing secrets are concomitant. Business ethics limits the practice, but there are conditions where good business demands that there be some migration with accompanying diffusion. Every plant manager knows that the employee who will sell the secrets of his former employer is not a safe repository for his own carefully guarded manufacturing methods. He is convinced that he must not start the subsidizing of crookedness by bidding higher for his competitor's men. But should conditions arise within the works of his competitor that caused men to resign of their own free will and come to him seeking employment he would be a weak business competitor if he did not hire any of them he wanted.

This very condition exists today between the German and American dye companies. There are a few German chemists who, recognizing that the monopoly, and consequent prosperity, of their home industry is at an end, are seeking to escape future adversity by migrating to American plants. The German Government sees its last grasp on this important industry being broken by this movement and has ordered the frontiers guarded and all suspected emigrant dye chemists arrested. Dr. OTTO RUNGER and Dr. JOSEPH FLACHSLANDER, however, got out of Germany and into the United States and are now working for the du Pont company. Shall these men be censured for disloyalty to the discredited German system of which they have been a part in the past, or shall they be allowed to make this their country? They cannot go back to Germany and re-enter the fold. They must make good here. To do so they must not be denied any reasonable opportunity nor be hampered by feelings of individual hostility on our part. Nor is American industry to be denied the opportunity to build for the future by the aid of individuals who, through changing economic and industrial conditions in Europe, choose to seek more attractive fields of endeavor. There are many such among us already.

In this matter of anti-German thought what we need most to keep in mind is the hazard of Germans together in large groups. Individual Germans are just like other people; German-born Americans are among the best of Americans. In a few years we hope that the danger of Germans in groups will be over. Suppose 100 German chemists were *bidden* to come here, and as a body to settle themselves in our industries. Singly they would probably be all right, and in time become useful citizens. But jointly, if they were inspired or instructed with the idea that their main business was for *das Vaterland*, that while engaged here in good faith they would secretly address themselves to the advancement of *deutsche Industrie*, then the suspicion might well arise

that neither the truth nor the comity of men nor decency nor even honor itself would have weight with them. We don't want Germans "planted" in groups in this country, but if German individuals choose to recognize a new order of things and cast their lot with us they should have an opportunity to show their good faith. As for their being a menace to American industry, we may confidently leave it to our big companies to protect their own interests and those of the country.

How Much Conceit Is Beneficial?

WHEN a young man finishes college and begins work in earnest, he finds himself the object of an indirect campaign to "take the conceit out of him." His elders and business associates see to it that he gets only such work and consideration as will show him how small he is in the scheme of things. If he doesn't have good luck and get promoted within a reasonable time, he is likely to feel downcast and to be glad to cling to the industrial machine by any kind of insignificant job. Especially if he has the temerity to marry within a year or two after finishing college and before he has established himself, he loses his conceit almost entirely and becomes as meek as any employer could wish.

The question is, Should young men be bullied out of their conceit? WHITING WILLIAMS, author of "What's on the Worker's Mind?" thinks that conceit is what makes complicated and highly specialized industry possible, and he advocates that employers encourage their men to feel their individual "worth-while-ness." He explains that the mechanic comes regularly to his bench and the millionaire to his desk, and make sincere, valuable citizens because each feels that he is an important part of the industrial fabric. Each one, though he has grievances and further ambitions, is proud of what he has achieved and can do, and this pride brings him daily to his work and adds zest to what otherwise would be drudgery. As an experienced personnel-manager, Mr. WILLIAMS suggests that this self-pride or individual conceit is the very basis of the social system. Labor unrest comes rather from the neglect of employers to permit their men this incentive than from differences about wages and salaries, says Mr. WILLIAMS. There are more foremen and officials who take unnecessary joy out of life than there should be for healthy conditions, is the conclusion of his book, written after seven months spent working as a common laborer in overalls. In other words, too many of the wrong kind of bosses have been promoted, and their driving, narrow ways have brought resentment. Common laborers, as well as young engineering graduates, have been given too little opportunity to feel the sense of individual worth-while-ness that Mr. WILLIAMS recommends. After all, as so many philosophers from PLATO to HERBERT SPENCER

have pointed out, each individual is the center of his own world. Everything revolves around the ego, in spite of temporary campaigns to discredit individualism. The most important thing to each man is himself. When he feels moderately happy, great accomplishments are possible; when he is browbeaten and depressed, he is a force for evil in the world.

The nation which has most encouraged individualism is England. Just as an example, a letter to the *London Times* generally receives respectful consideration both from the editor and from a wide circle of readers; they have learned that excellent suggestions are made in that way, that national benefits accrue from permitting individuals to express themselves, as the canny ADAM SMITH long ago pointed out. In spite of the hamperings of class distinctions in British society, individual genius is probably more quickly recognized than in America. Those in control of things there are influenced by a tradition to help original thinkers who appear to possess talent of value to the nation.

In America there is, of course, what is called "rampant individualism," but it results in everyone being so busy with his own affairs or so shortsighted in his own troubles that the young man of exceptional talent is as likely to remain unrecognized as not. Why was it, for instance, that HERBERT HOOVER found more scope for his extraordinary ability in London than in America, at least until he was a well-known and successful engineer? Without doubt, if he had been a more conventional type he would have found plenty of opportunities in this country, but because his combination of gifts was of the kind that the ordinary American employer did not recognize, he found more attractive openings in British firms directed from London.

Taking a historical case, the record of BENJAMIN THOMPSON, who died over a century ago, shows that that notable scientist and administrator found instant recognition and encouragement in Europe, where he was made Sir BENJAMIN THOMPSON in England and Count RUMFORD in Bavaria. In America, although he was of an old New England family, he encountered only enmity and jealousy. It is true that he left his fortune to Harvard College, but most of his work benefited Europe, since he founded the Royal Institution in London and has a statue to his honor in Munich. It was a pity that America did not profit more by his unusual talents in both pure and applied science—such as his researches in the physics of heat and his experiments with explosives.

These are not the only Americans who have found greater success abroad than was possible in their own country. Many others could be mentioned, and many more who never had the chance to try their fortunes abroad undoubtedly would have succeeded better there than here. In other words, Europe is quicker to recognize certain kinds of talent than is America, not only in literature and art—as is commonly admitted—but also in engineering and general science. America is quicker than Europe to help certain other kinds of ability; we all know of immigrants who have amassed a fortune in short order. But the point is that it is more important to recognize ability among native Americans, such as HOOVER and THOMPSON, than to make the fortunes of Italian or Russian immigrants. The good that a great constructive thinker or critic can do is more essential to the nation than is the operation of the corner fruitstand or the business of a get-rich-quick Ponzi.

America's first consideration should be encouragement for her own young men to express themselves in ways helpful to national interest.

That young men are conceited is an excellent sign. Instead of bullying them into forgetting their ambitions, the men in control of industry should take youth more seriously and train it more broadly and more sympathetically, granting opportunities that appeal to the adventurous and eager. In Germany, before 1917, visitors remarked that when the Kaiser or his generals passed down the street, people literally held their breath. That was conceit grown unhealthy beyond all reason, but the moderate conceit that Mr. WILLIAMS advocates is healthy and beneficial.

Metallurgical Mysteries

FEW are so dull who are not at some time or other impressed with the mysterious things with which they work and the mysterious changes taking place under their guidance. In olden days, more simple minds were often overpowered by the strange and unexplainable on all sides, and saw at times the hand of Deity. Today, we more sophisticated talk about the size of the stellar system and the energy in a radium atom just as though the infinite were conceived by finite minds.

But fancy how dull and uninteresting things would be if everything was known about them—the precise facts of their constitution and the exact action under all conditions. Metallurgy may be and doubtless is dull and uninteresting to many who know hardly how to pronounce the word, but how dull it would be even to those who know most about the art if all the mysteries were solved! Real mysteries, not those pseudo-mysteries which one often meets. Such as a locked door which conceals some trade secret—more often than not a process known to many and discarded by them years ago for a better. The fence erected to keep out inquiry too often coops self-sufficiency and ignorance. Or such another myth as "body" in steel—that indefinable something which makes an octagon bar labeled in gilt better than a round one stamped in black.

Granting that the limit of human achievement is merely to push a little farther back the boundary between the known and the unknown and that there will always remain a vast residue of darkness, still it is surprising at times to take stock and find that every branch of metallurgy practices daily large-scale operations about which our precise information is pitifully small. Why do heavy mineral particles float in a Callow cell? In what way are metals entangled in slag and never recovered? Why should humidity play such an important part in the electrical precipitation of fume? What is the nature of the forces acting between white-hot metal and gas, forces underlying all steel-making processes? What is the nature of hardening or of season cracking?

Of course such problems are highly complex. A tremendous amount of work has already been spent upon them, and still there is no conclusion. Their final solution will probably call forth scientific knowledge and resources of high order. But there are many problems somewhat simpler which can be attacked with more modest equipment. As instances: Why does a copper plate prevent case carburization; is it because the thin covering is impervious to carbon monoxide, or is copper

more active than iron in extracting carbon from that gas, so that there is little left for the iron underneath? Why does cupola-melted white cast-iron require a higher annealing temperature than the same metal melted in an air-furnace; is it because of higher sulphur or finer grain? Why should either affect graphitization? Why does quenched silicomanganese steel made in the open-hearth require a draw 100 deg. higher for equal hardness than metal of the same analysis from the electric furnace? Is it due to extra nitrogen in open-hearth steel; is it due to strange carbides formed in local hot-spots under the electric arc; or is it merely due to the better separation of laminar pearlite usually found in such electric steels?

One might proceed to enumerate many such problems, all of intense importance from a commercial viewpoint. Some of them are under active investigation, such as sulphur and phosphorus limits in tonnage steels, brittleness of steel at a blue heat, and the relationship between fatigue and other physical tests. Others deserve closer attention than apparently they are getting. Why should the common alloy steels acquire "temper brittleness" if slowly cooled after drawing? Why should quenched mild carbon steels after drawing at 400 deg. C. give maximum strength, hardness and solubility in acids? The latter fact has been long known and associated with a peculiar microscopic appearance sometimes called "Osmondite," yet the phenomena do not occur in higher carbon steels. Silicon, phosphorus and aluminum all increase the grain size in steel castings. If a sound, but used, spring be given a heat-treatment similar to that which it originally received, its subsequent life is greatly shortened. Why?

Perchance some who read these lines will attack one of these problems in a systematic way. They will then find a new interest in their workaday life.

Byproduct Coking

Establishes Another Record

IN 1920 the byproduct coke production of the United States was approximately 30,700,000 net tons. This is an increase of 22 per cent above the output of the previous calendar year, the result of many influences, among others the fact that 850 new ovens were put into operation during the year. Not only was the quantity of byproduct coke greater than ever before, but also the percentage of the coke output produced in byproduct ovens increased to practically 60 per cent of all, only 40 and a fraction per cent being made in beehive ovens.

Whether 1921 will show a continued increase in coke tonnage or not will depend upon many economic factors beyond the ken or even the guess of the most learned prophets. However, it is safe to say that the percentage of coke made in beehive ovens will for some time continue to decrease. Indeed, it is to be hoped that a decidedly lower percentage will be made by this process each year until we can say that the beehive oven is only a negligible factor in the situation. Simultaneously, of course, the byproduct oven output will increase in both quantity and percentage.

It is too much to ask that all fuel be processed, for if all our bituminous coal could be treated in coke ovens, which it cannot, there would be no adequate market for many of the byproducts. We could, of course, use all of the light oil as motor fuel; in time we might absorb all of the tar as a Diesel engine fuel or as a petroleum

substitute; and too, the market for nitrogen would care for all of the ammonia produced (presumably to the exclusion of Chilean nitrate) if the fertilizer demands were carried to the limits proposed by experts in soil improvement. However, the economic conditions permitting such tremendous developments would not justify the necessary large investment in coal-processing equipment. It is well to bear this fact in mind and not be rushed off our feet by the theoretical advantages which can be so glibly recited in favor of coking on a large scale.

Reasonable encouragement should be given to the coking of coal, so that the market for byproducts may be amply supplied and inducement offered for the maximum utilization of these valuable chemical raw materials. In the meantime, however, it should be clearly recognized that the development will be gradual rather than spectacular. And through it all there should be a progress from year to year that will be most encouraging to both byproduct producers and to the industries using their products as raw materials.

Brains Applied

To Forging

DETAILS of a hundred kinds impress one with the Herculean efforts France made seven years ago to stop the German attack. Once stopped, and taking stock of her resources, she found the enemy in possession of 70 per cent of her metallurgical works. This at the very outset of a war, won undoubtedly by human courage and sacrifice, but nevertheless a war between special engines and machines of great power and wide variety!

That eminent French ironmaster EUGENE SCHNEIDER has recently made several allusions to the progress, construction and intensive production which was necessary in order that their troops could be properly supplied with munitions. In his presidential address before the 1918 meeting of the British Iron and Steel Institute he alludes to the startling savings made possible by every attention being given to eliminate unnecessary delays in fabrication. "Two compressed-steel ingots, weighing respectively twenty-one tons, were selected, as they came from the molds, to be forged into three 220-mm. Schneider mortars and one 155-mm. Schneider howitzer. Particular attention was bestowed on the former through all forging operations; the latter was left to the current routine of the gun shop. Now, whereas it took eleven and one-half days and seven heatings, plus one of annealing, to transform the former, for the latter forty-three days and nine successive heatings, plus one of annealing, were necessary. The expenditure in fuel was, therefore, more considerable for the latter, but especially there was ample scope for the elimination of the so-called dead stops."

With three-quarters of the plants gone, France of course strained every effort to construct new and modern works far to the rear of the battle zones; but waiting their completion, a close attention to operating details was evidently able to increase the apparent capacity enormously.

While he does not say as much in so many words, undoubtedly the recorder he described last fall, and briefly noted in this issue, was of great help in such a remarkable saving in time. It is a happy augury that tradition, which excludes sunlight from a forge shop, has been unable to prevent the entrance of common sense.

Readers' Views and Comments

Shall Chemists Be Registered, Certified and Legalized?

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to your editorial, "A Question That Will Not Down," in your issue for Feb. 2, I think that the views there expressed are very much to the point, and I agree with you that the scheme of listing and certifying chemists had best be tried out first in New Jersey. I question whether it is really necessary to start a new organization such as the proposed Institute of Chemistry. Could not the matter be handled by one of the existing chemical societies, either the American Institute of Chemical Engineers or the American Chemical Society? That new, live organization, the New Jersey Chemical Society, is most earnestly interested in the question, and undoubtedly can do much by trying out the idea in its own state.

The main issue, as I see it, is not only "Who is a chemist?" but "How to tell the general public who is a chemist." Members of the chemical and allied professions and industries employing chemists need no Institute of Chemistry to recommend men to them or tell them where to procure certain materials. The general public, on the other hand, have a very vague idea as to how to proceed. Their only source of information is the daily press and the *Saturday Evening Post*. Probably they have never heard of our chemical journals nor of the Chemical Catalog nor of that handy little annual published by Williams & Wilkins of Baltimore.

My suggestion is to have the New Jersey Chemical Society do some advertising. This may bring forth adverse criticism on the ground that it is unethical for a scientific organization to advertise. Nevertheless, if the advertising be done discreetly, the objections will easily be overruled. The society might insert a small notice in the *Newark News* throughout the year informing the readers that anything pertaining to chemicals or chemists can readily be ascertained through the society.

South Yonkers, N. Y.

COLIN D. FINK.

Should Start Within American Chemical Society

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to your editorial on the proposal of the New Jersey Chemical Society to organize an American Institute of Chemistry, I wish to say that I have already had some correspondence with the promoters of this plan and have strongly advised the desirability of not attempting to have the tail wag the dog, but to get the dog to wag the tail. In other words, a small society should not take upon itself the burden of starting a big institution which it would be difficult for even the American Chemical Society to start. I think it would be far better if the movement should start from the parent society and not from one of the smaller organizations, because the men of reputation in the country will hardly like to go into an august body, such as this would be, through the back door.

The origin of the Institute of Chemistry of Great Britain is along much the same line as the plan which

has been proposed recently in this country. A certain section of the Chemical Society in London was under the impression that the highbrow stuff read and published by the Chemical Society was not exactly what was needed for a consulting chemist. Several of the latter tried to get the Chemical Society to form a section through which consulting men could be known to the country as experts in certain lines. The highbrows in the Chemical Society said that any man belonging to it was guaranteed as being the finest man in his profession, to which the others replied that all that was necessary to belong to the Chemical Society was to get three members to sign a paper, and pay one's dues yearly, which any office boy could do. As a consequence a few of them got together between thirty and forty years ago and formed the nucleus of the Institute of Chemistry of Great Britain, and after they had been in existence for a time they managed to obtain a Royal Charter, which gave them power similar to that exercised by the universities—in a measure to grant a degree, which was given only after an examination. The self-appointed nucleus of this organization, being men of reputation and in most instances well known to the country at large, exercised great care and diligence that no office boy or similar person was admitted during their organization of the society. When the Royal Charter was granted all free admissions were stopped, and entrance was obtained by examination only, a practice which obtains to the present day.

The objects of this society were to raise the standards of the consulting man and generally see to the ethics of the profession; and I think I am not wrong in saying that any Fellow of the Institute of Chemistry of Great Britain is an exceedingly high-class man and can always be relied upon in any class of work which he undertakes. Should he get into work for which he is not quite competent, all he has to do is to go to one of the other Fellows who stand always ready to help him. All chemical offices of a public nature in Great Britain can be obtained only by Fellows of the Institute of Chemistry. Only in very rare instances are chemical posts given to other men, and during the war this was very much accentuated.

You will remember there was a similar movement on foot here some years ago, but instead of starting with the parent society, the American Chemical Society, a certain few broke away and started the American Institute of Chemical Engineers. I do not think that the chemical engineers are the right people to have charge of such a movement as the New Jersey Chemical Society proposes, nor do I think that the New Jersey society itself is the right place to start it. It should be done within the body of the American Chemical Society and certain selected men within that body should be formed into a section of consulting chemists, which would raise the standards of that class of chemists and would after a time institute an examination whereby only those fitted could become members. There would be a very great advantage in having such a society as this, because at the present time it is almost impossible to recommend a suitable man to a client, unless one happens to be

personally familiar with the records of a large number of men. In any event, there is no official record, and one has to trust to memory and hearsay, as to what this or the other man does or is competent to do.

A FELLOW OF THE INSTITUTE OF CHEMISTRY
New York City. — OF GREAT BRITAIN.

Register, Perhaps Certify, But Not Legalize

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to the proposal to form an Institute of Chemistry, I feel that the American Chemical Society now possesses a very good list of all the chemists in the country, though I am sorry to say that it contains the names of some who do not stand high. I would like to see the American Chemical Society's membership revised into chemists and associates, and have the former picked by a good committee. This would cover the first two points proposed in the scheme of the New Jersey Chemical Society—namely, listing and registering. As for certifying, this also might be worked in.

In the matter of legalizing, however, I am not sympathetic. I know that plumbers are legalized, but plumbers are robbers; doctors are legalized, but their patients pay for their mistakes; undertakers are legalized, but they bury the mistakes of the doctors. I believe that chemists should be able to demonstrate a high standing to such an extent that they will not need any legalizing.

New York City.

DAVID WESSON.

Need for Complete and Classified List

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to your editorial on the proposal to form an Institute of Chemistry, I am inclined to agree with your opinion. I think, however, that the plan has several good points, and suggest that Dr. Crane talk to the Council of the American Chemical Society about them.

While in Washington during the war, my work brought me in contact with chemists all over the country, and at that time an alphabetical list was made of all chemists in the service as well as out of it. I had hoped that this index might be kept up, and by combining it with the data secured by Major Breithut and the records held by Dr. Parsons, it would have been a comparatively easy matter to make a complete list of all chemists in the country and classify them according to their qualifications. I should like to see something of this kind carried out, as I believe it would be of great benefit to American chemical industries.

Brooklyn, N. Y.

ALLEN ROGERS.

Certification a Difficult Problem

To the Editor of Chemical & Metallurgical Engineering

SIR:—Replying to your recent letter regarding the advisability of organizing an American Institute of Chemistry, I would reply that the subject is a complicated and difficult one to handle. The New York Section of the American Chemical Society was troubled with the same problem about fifteen years ago, and after considerable study and discussion of the question decided that it would be inadvisable to attempt anything of the kind at that time. Of course, it does not necessarily follow that it is therefore inadvisable at the present time.

Superficially, the question appears to fall naturally into two main problems: (1) Registration; (2) certification. For purposes of registration, the proper place,

in my opinion, is the office of the secretary of the American Chemical Society, where there are already available the results of the extensive census of American chemists conducted by the Bureau of Mines during the war. In addition there is all of the material collected by the Chemical Warfare Service. The secretary's office could without very heavy financial expense function as the repository of the biographical records of all such chemists as may be willing to supply the requisite information concerning themselves.

The problem of certification is much more difficult and one which I do not feel the American Chemical Society can safely undertake without danger of disrupting its organization. The great success of our society has been due to its simple democracy, there being no distinctions of any kind attempted between the various groups of members. In years gone by such discrimination was attempted and we had active and associate members. The result was very unsatisfactory and as soon as this discrimination was dropped the society began to go forward by leaps and bounds, until it has reached its present proud position of being the largest chemical society in existence.

To undertake the creation of an Institute of Chemistry, presumably modeled along lines similar to those of the Institute of Chemistry of Great Britain, is a serious undertaking, and we must be clear in our own minds that the situation justifies it.

Would Advertise Profession of Chemistry for Public's Education

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to your editorial on "Who Is a Chemist?" in which you comment on the proposal of the New Jersey Chemical Society to found an American Institute of Chemistry, I wish to say that a good many years ago I was chairman of a committee of the American Chemical Society which considered this same question and reported that in its opinion it was undesirable either to license a chemist or to form an Institute of Chemistry such as existed in England. The committee was of the opinion, however, that it would be desirable for the American Chemical Society to set up a branch of its membership which should take the place of an Institute of Chemistry and perform such functions of the British Institute as were practicable and desirable in this country.

Bearing on this subject, I have recently written to Dr. Crane of the New Jersey Chemical Society substantially as follows:

The first question one naturally asks about this matter of forming an Institute of Chemistry or of licensing chemists is, What is it designed to accomplish and what needs would such a movement fulfill? The answer seems to be that today there is nothing to prevent any man, whether he is wise or ignorant, able chemist or charlatan, from hanging out his shingle and advertising himself as a chemist. At the same time, before a man can practice either law or medicine he must have attained a fairly high standard and must have been legally recognized. Furthermore, even plumbers and chauffeurs must prove their fitness to act in their respective capacities, or otherwise we should be poisoned with sewer gas or constantly threatened with loss of life on our streets. The real question is whether the employment of a chemist involves risks to the employer that are comparable to those taken by the public in employing a

lawyer, physician or chauffeur, and furthermore, whether these risks can be removed or greatly minimized by examining chemists and thus separating the sheep from the goats.

The relation of the chemist to the public is now such a complex one, and the services now rendered by chemists and to be rendered in the very near future are so varied in character, that it is difficult to see how any examination could cover the field. If it did so adequately, few could begin to pass it, and probably the few who could do so would be by no means the best men.

So much for legislative regulation as to the fitness of chemists to practice their profession at all. The plan of forming an Institute of Chemistry which shall guarantee only that its members have in the first place an extensive knowledge of general theoretical chemistry, and, if it seems desirable, also guarantee that certain classes of its members are expert in this or that branch of chemical practice, rests upon an entirely different and surer footing as long as it does not attempt to make a closed shop of the country and deny to non-members the right to work if they can find employers. The serious difficulty between the chemists and the public today is the lack of understanding by the public of the nature of the services which the chemist can render. Restrictive legislation does not promise anything like a remedy for this, but the American Chemical Society already is doing much, and perhaps an Institute of Chemistry, if it should undertake this task, might accomplish more. The question seems to resolve itself into one of properly advertising the profession of chemistry, letting the public choose who serves it best. It is only the chemists who can teach the public that their services are necessary and valuable, and the plans outlined by the New Jersey Chemical Society may be judged by the test of whether or not they are to further this teaching.

New York City.

PARKER C. MCILHINEY.

Plan Should Be Tried on a Small Scale at First

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to your editorial on "Who Is a Chemist?" and the proposal of the New Jersey Chemical Society to start an American Institute of Chemistry, I wish to say that such an institute if started should have a small geographical scope. An organization covering the State of New Jersey probably will be large enough; perhaps a county or a few counties will be big enough for a beginning. In other words, I favor a kind of test-tube experiment first. Conditions vary so from city to city and state to state that I am convinced that the inauguration of a national body in the beginning would fail and unnecessarily delay national standardization far beyond the time at which it can be accomplished if started in small units in different states or localities. Let the New Jersey Chemical Society try to standardize things for, say, the Newark district and then spread out from there. This process would bring to light a lot of concrete facts that would help solve the national problem.

As for some of the other things which it is proposed to accomplish, why not assist the present agencies to do them better, rather than inaugurate something new? Thus in the proposal to list all chemical products, why not help out the Condensed Chemical Dictionary? And as for listing all chemical industries, why not help Dr. Lovelace keep the Annual Chemical Directory up to date

and properly enlarged instead of competing with him? It seems to me that the New Jersey Chemical Society could contribute a great deal to the subject by outlining in the form of a law the necessary requirements for the general or specific practice of chemistry. Here again they might begin with a small district, such as Newark, and then try it for the State of New Jersey and see if the state will pass such a law.

*New York City.

BERNHARD C. HESSE.

Futility of Examinations

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your editorial, "A Question That Will Not Down," in the Feb. 2 number, the sentence, "As for the certification feature . . ." brings up a very vital question, Who is really competent to judge the correctness of answers to questions dealing with industrial subjects? We have many men in the chemical, as well as in other sciences, with advanced ideas, which are not common property. A set of examination questions can easily (and quite unintentionally) ask for such knowledge, which the candidate has made a special study. If he answers to the best of his ability, he would be publishing information which others have been seeking unsuccessfully. If his answers are only on the basis of published information, they may be considered insufficient due to special knowledge by one or more of the examining board. Furthermore, technical questions are often a matter of opinion due to varying conditions. What is excellent practice at one point, due to conditions, must be condemned elsewhere.

Another phase of this question is how such an examination would be conducted. Would the candidate be compelled to rely solely on what he carries in his head or would his knowledge of where to find information also be considered? This latter source of knowledge is often much more valuable than the former, otherwise we would have very limited use for reference libraries. A recent advertisement for an experienced industrial manufacturing chemist at \$80 to \$100 per week specifying "Must pass preliminary examination without reference to handbooks" certainly expresses the opinion that only memory of facts, and not the ability to find facts, is knowledge.

Are we not treading on very thin ice?

Newark, N. J.

HERMAN S. RIEDERER.

Causes of Corrosion of Copper and Brass

At a recent meeting of the Birmingham and Midland Section of the Society of Chemical Industry, Dr. O. F. Hudson, of the Admiralty Research Laboratory, said that he believed electrochemical action was not the sole cause of corrosion in the case of copper and brass, and that in most cases, in neutral or slightly alkaline solutions, that action was relatively unimportant, the greater part of corrosive attack in these cases being due to direct chemical action. In acid liquids, and industrial waters which had a distinctly acid reaction, electrochemical action might play a more important part, but in such cases the metal—e.g., condenser tubes—failed by general thinning rather than by pitting or localized attack, which was in other cases generally the chief trouble. Electrolytic protection processes probably owed their efficiency largely to the production and maintenance of a uniform resistant scale of calcium carbonate. There was little hope of finding an alloy which would resist corrosion under all conditions.—*The Engineer*, Dec. 17, 1920.

What Chemistry Can Do in the Food Industry

A Concise Dissertation on the Broad Field of Work That Is Open to the Chemist in the Food Industry and on the Beneficent Results Derived From the Application of Chemistry to Obtain More, Better and Cheaper Food

BY R. S. HILTNER*

IN THE industry of food production, nature and science have always been true helpmeets and must necessarily be such. Since 1912 the knowledge of food and of the essential principles of animal feeding and nutrition has been marvelously clarified. Such competent investigators as Funk, McCollum, Osborne, Mendel and many others (Seidell, Morse, Talbot, Hogan) have turned a deep-penetrating searching light on the subject and have discerned many facts as to the true nature of food and the dietary requirements of the animal body. Those men and others not mentioned have shown by their discovery and study of vitamins, food accessories, that in reckoning the feeding value of food we must consider more than the mere calorific coefficients and the empirical composition, the percentages of fats, carbohydrates, protein and mineral salts. They have shown that certain natural foods—eggs, milk, green vegetables, mature fruits, for example—contain substances that are absolutely essential to growth of the animal body—dumb brute or human. Without those substances the body would soon become scurried, would wither and die, even though fed with fat and protein and sugars and inorganic salts.

They have shown that those classes of food components, though closely approximating each other in chemical composition, differ widely in their nourishing powers. We know now that all proteins are not alike in nutrient quality and digestibility. The fats and oils, while similar in their proportions of carbon, hydrogen and oxygen and in their heat values, vary widely in flavor, palatability and assimilability. Even the carbohydrates are not in agreement as to food value. The starches differ from the hydrolyzed bodies, and, what is more, the sugars having identical empirical composition are variable in value as foods. The aldehyde sugars—for example, dextrose—are not like the ketone sugars, such as levulose, in food quality. Recently it has been shown that the starches of various plants are dissimilar in chemical composition, and by inference we may conclude also that they are not quite alike in food value. We have been wont to believe that starch is starch—a carbohydrate strictly so. But starches contain phosphorus largely in carbohydrate combination¹ and in varying amounts. Potato starch contains about 0.15 per cent total phosphorus computed as P_2O_5 , while corn starch contains only 0.03 per cent.² Obviously, therefore, the sugars produced from the different starches by hydrolysis have somewhat un-uniform composition and probably variable nutritive value.

These facts—some newly discovered and some long known—possibly somewhat unrelated to the subjects are

set forth here as a framework for the answer to the question, What can the chemist or chemistry do in the food industry? The activity of the chemist in the food industry naturally resolves itself into three or more phases. Analytical control is one, technical and engineering another, and investigation and research another. All are important and it is difficult to say which is the most essential to progress and success of the industry. The analyst's part in the industry is easily understood. It is important work. The chemist-analyst is the controller of the industry. He holds forth the guiding hand. The function too of the chemical engineer is clearly defined. We look to him for results in matters of production and quality of output and for constructive suggestions relating to improvements in technique and general procedure.

What the chemist investigator can do to benefit the industry is quite another matter. It is the kernel of the inquiry. When we speak of the food industry we quite intuitively think of food manufacturing. But, strictly speaking, is there such a thing as food manufacturing or can there be? Do not the electricians' terms "transformer" and "transforming" apply more aptly? No one has ever made a fat or an oil, though the chemist has learned how to transform them and refine them and make palatable food-fats out of unpromising products. No one has ever manufactured a protein or a starch. Nature's barrage has been so dense and so baffling in this respect that few, in recent years, have had the courage to attempt to penetrate it. The production of the fundamental food elements seems to require nature's own handiwork. No true-hearted chemist should ever allow himself to cry "it can't be done," or permit himself to be checkmated, or to throw up his hands and quit while the breath of life remains in him. But thus far the "game" has been practically lost by all who have played it. The nearest approach to winning against natural forces—and this may be said for the encouragement of the chemists who will still try—is in the synthesis of a few of the sugars and of some of the organic food-acids. Despite all the efforts that have been made we are forced back into the groove of thought of chemists prior to Wöhler and are thinking and saying that nature does and must play an important part in the production of "organic" chemicals. As a matter of fact, and strictly speaking, all foodstuffs are "organic" chemicals, simple or complex compounds or mixtures. Salt is perhaps the only exception, though it is not really food. The ash, frequently spoken of as "mineral matter," derived from foods by incineration, does not exist in foods, *per se*, but in combination with organic acids, protein, etc.

The discoveries of vitamins by biological chemists recently have also served to upset the calculations of many an ambitious chemist who would produce foods

*National Canners' Association, Denver, Col.

¹Northrop and Nelson, *J. Am. Chem. Soc.*, vol. 38, p. 472, February, 1916.

²R. S. Hiltner, National Canners' Assn., and H. J. Wichmann, U. S. Dept. of Agriculture, Bureau of Chemistry; unpublished article.

artificially and synthetically and even of the less scientific and pretentious food manufacturer or transformer, if you please, who would elaborate some strange raw product into acceptable food.

NATURAL FOODS VERSUS CHEMICALLY MADE FOODS

The proof recently secured that butter fat is far superior as growth-producing food to other oils and fats is as interesting and valuable as it is disconcerting to the chemist. Who can say at present that those acids and those sugars that have been produced artificially are as good foods as those elaborated by nature? The presence of food accessories, minute in amount but mighty in force and effect, in natural foods still keeps them at a high premium above any that chemistry has elaborated. Perhaps after all it is just as well that it should be so. The kitchen is not the normal place for the chemist. Trained appetite will not willingly open its mouth for chemical food. The layman in his mind associates chemicals with poisonous acids and vile smells and wants none of them for food. God-made foods are to be preferred to man-made.

THE SCOPE OF THE CHEMIST IN THE FOOD INDUSTRY IS FOR GREATER EFFICIENCY

If, then, the chemist yield to the thralldom of Nature and admit that she is the supreme artisan and compounder of food, what is there left to him as a scientist to accomplish in the food industry? The most sensible answer seems to be that he continue his course, outward and upward, working out his schedule, striving for greater and greater efficiency. That course has never been along the smooth road marked with signposts, but off the trail into regions unexplored. His schedule in the food industry has never comprised, as an essential part, the fanciful plan of elemental construction of foods, but rather the scheme of refining natural products and finishing raw materials. Extracting foods rather than manufacturing them has been the accomplishment of chemistry.

The refining of sugar from the sugar beet and the recovery of byproducts is one of the most notable achievements of chemistry, as applied to foods production. Out of raw juice of the beet, complex in its make-up, by the use of simple and inexpensive reagents a food is recovered practically chemically pure. There is a splendid example of food chemist efficiency. Therein lies a suggestion for further work. The human appetite craves sugars; the animal body requires them. They must be extracted from raw products or else built up from other products. Substitutes there are none and can be none, any more than there can be real substitutes for butter, for eggs, or for the protein of meat. The tongue may be fooled, but the stomach never.

The demand for sugar is ever increasing. To meet it the sugar chemist should do his part. Increased production will come from closer communion and co-operation with Nature on the part of the chemist, the plant-breeder and the farmer. The scientist in the laboratory and the scientist on the farm must keep in touch. The two must study and develop species of plants now unused for sugar production. They must not overlook the starchy roots that can be converted into sugars—the “cat-tails” and sweetflag of the roadside bog may be cited, in passing. They must not forget the possibilities in other roots and tubers. The Jerusalem artichoke, the dahlia bulb, the chicory

root contain inulin, kindred to starch, capable of yielding a sugar, levulose, sweeter far than glucose.

He who takes the lead in these matters must be possessed of a fine courage, must let his fancy take flight, must be willing to risk well-earned reputation, must “take a chance.” The sugar chemist must study deeper into mysteries of carbohydrates. He must know cellulose better. That stubborn substance, the framework of plants, itself a carbohydrate closely related to starch and sugar, should be converted or transformed into sugar. Speed the day when a sack of sugar can be evolved from a bale of straw! Progress along this line has been made recently in the U. S. Forest Products Laboratory at Madison, Wis.³

WHAT THE CHEMIST CAN DO IN THE FOOD INDUSTRY

The animal continually clamors for food. In the words of the nursery jingle, “Please give us more and more and more, such hungry birds I never saw.” It is not the cry of greed, but the call of need. Chemistry more than any other science can aid in supplying that demand, especially so far as human food is concerned. The ox relishes raw cane, but man must have refined sugar; the wild animal prefers the blood and vital organs of his prey, but man chooses “dressed” meat.

The sugar chemist has a part to play in meeting that requirement; the oil chemist a part and the protein chemist a practical rôle. Many problems are yet unsolved and there is room for each to do his best.

Someone will soon learn how to make better glucose—a drier, whiter, sweeter product from starch. Someone will improve the present sugar and recover more from the raw material. Someone will develop a better process for gelatine and produce a cleaner, more wholesome article. Someone will make still further advances in transforming and refining edible oils, and make more oils fit to eat.

Chemists are learning more and more about catalysts and enzymes and ferments and will use them more in the future in producing new foods or better products.

Some day chemistry will discover the way of extracting vitamins from bulky produce and concentrate them in acceptable forms in foods. Chemistry will improve the art of preserving foods by canning, by drying, by concentrating, holding color and flavor and food quality intact. Paradoxical though it sounds, the chemist will teach us how to transform, preserve and conserve foods without the use or introduction of chemicals. For the dried fruit industry he will discover the way without using sulphur to destroy the enzymes and prepare the product so that the eye of the consumer will be pleased and the palate not offended and health not deranged. For the miller he will find a better means of bleaching and “aging” flour. For the butcher he will learn better technique in preserving meat, avoiding chemicals and dyes. For all he will constantly watch for “leaks” and devise better schemes for preventing wastes and for utilizing byproducts.

These things are not said as prophecy, but because of an abiding confidence in the ability of the chemist to accomplish whatever he diligently seeks to attain. He will answer the call for more and better and cheaper food. In his efforts to achieve these things, let him emulate the aviator, unafraid, striving for altitude records, braving the cold lonesomeness of the higher levels and minding not the withering winds of ridicule.

³See CHEM. & MET. ENG., vol. 24, No. 4, p. 160, Jan. 26, 1921.

Electrolytic Zinc Plant of the Anaconda Copper Mining Co., at Great Falls, Mont.*

Utilization of Sulphate Roast to Save Leaching Acid—Insoluble Zinc Ferrates in Iron-Bearing Calcine—Coagulation, Granulation and Filtration of Silica and Other Impurities From the Zinc Solution—Slime Purification—Dross and Residue Treatment

ABOUT six years ago the Anaconda Copper Mining Co. decided to investigate the possibility of extracting zinc from the complex ores of Butte containing so much iron and lead that the concentrate analyzed only 33 to 35 per cent zinc. After a careful preliminary study it was decided that the electrolysis of sulphate solutions was the most promising method for zinc recovery. It was soon found that to obtain a good zinc deposit an electrolyte is required free from all metals more electronegative than zinc, such as copper, cadmium, lead, arsenic or antimony, etc. Arsenic and antimony are particularly injurious, causing very small yield per horsepower when present in amounts so small as almost to defy detection—1 mg. or less per liter.

It was not found difficult to maintain an extremely high degree of purity in the zinc solution going to the cells if the iron content is thoroughly oxidized before precipitation by means of limestone or excess calcine and if sufficient zinc dust is added to satisfy the copper, cadmium and whatever small amount of lead might be present. It may be necessary to add a ferric salt to low-iron solutions to insure the complete precipitation of all arsenic as ferric arsenate. The best way to make sure of the oxidation of the iron is to maintain a small amount of manganese in solution; it becomes oxidized in the cells to permanganic acid, manganic sulphate and manganese dioxide.

An aluminum plate makes the most successful cathode and a lead plate the most suitable anode. The latter becomes coated with a brown layer of manganese dioxide and lead peroxide, but if the electrolyte is entirely free from chlorides the lead is not attacked; anodes used three years seem as good as new. Zinc starting sheets proved unsatisfactory, as the sheets warped and caused short circuits.

Forty-eight-hour sheets weighing about 20 lb. (40 lb. per cathode) are generally made. Heavier cathode deposits become roughened, due to sprouting, and also tend to break contact between sheet and the aluminum plate.

In practice the most satisfactory current density is from 22 to 25 amp. per sq.ft. Evolution of gas at the anode is then sufficient to provide the necessary agitation.

After working in the laboratory for more than twelve months a 10-ton plant was erected at Anaconda, but by making changes its output was increased to twenty-five tons per day. The plant went into commission about the first of November, 1915, and was operated with considerable profit for a year. On Dec. 13, 1915,

ground was broken for a 100-ton plant at Great Falls; this plant began operations on Sept. 11, 1916, and was completed in December. In 1918 the plant was enlarged to make 150 tons of zinc per day.

ROASTING DIVISION

At Great Falls there are fourteen roasting furnaces of the Anaconda-Wedge type. As the 1918 extension called for more roaster capacity than was available at Great Falls, fourteen 20-ft. McDougall furnaces at Anaconda were converted into zinc roasters. Each furnace has two fireboxes, one on each side of the seventh hearth. Powdered coal is blown into the fireboxes under 12-lb. pressure.

This plant was started on the oxide roast as developed at the Anaconda experimental plant. When the new zinc plant reached full capacity, the sulphuric acid plant at Anaconda was unable to supply the leaching acid, so it was decided to try again sulphate roasting, unsuccessful in the 25-ton plant at Anaconda. As the result of a series of tests, which demonstrated that a sulphate roast was practicable, all furnaces were put on sulphate roasting with a 40-ton feed per twenty-four hours, with results as plotted in Fig. 1. The slower speed of the rabble arms and low temperature resulted in a big reduction in furnace repairs which more than compensated for the slight increase in fuel and for handling the doubled weight of flue dust. Apparently there is a decrease in silver volatilization with sulphate roasting because silver recovery has been higher at Great Falls than at Anaconda.

Much has been said about the difficulty of roasting iron-bearing concentrates, so as to render the zinc soluble. It was found that insoluble zinc compounds are undoubtedly formed and the percentage of zinc that remains insoluble increases with roasting temperature. However, it is not difficult to

ZINC ELECTROLYZING DIVISION

Operation of lifting frames and method of cathode removal

*Abstract of a paper to be presented Feb. 14, 1921, before the N. Y. meeting of the American Institute of Mining and Metallurgical Engineers by Frederick Laist, manager Reduction Works, Anaconda Copper Mining Co.; F. F. Frick, research engineer Anaconda Copper Mining Co.; J. O. Elton, assistant general superintendent Great Falls Reduction Department, Anaconda Copper Mining Co.; R. B. Caples, assistant superintendent Great Falls Reduction Department, Anaconda Copper Mining Co.

FIG. 1. ROASTING LOW-GRADE CONCENTRATES IN WEDGE FURNACE

make a calcine containing 82 per cent of its zinc soluble in 2 per cent sulphuric acid, from a concentrate that contains 33 per cent zinc and 20 per cent iron. An excessive temperature (more than 600 to 625 deg. C.) will reduce the efficiency to 60 per cent. A concentrate containing 50 per cent zinc and under 5 per cent iron will render soluble about 94 per cent of its zinc. (Fig. 2.) The temperature may be greatly increased on low-lead concentrates which do not sinter.

The McDougall furnaces at Anaconda have consistently given about 3 per cent higher solubilities than the larger Wedge furnaces; the former are equipped with dust collectors and have the firebox on the sixth hearth. The Cottrell treater, being placed just over the furnaces, precipitates sulphur trioxide with the flue dust which is returned hot to the first hearth of the furnace when the treater plates are rapped. This sulphur trioxide appears to combine with the moisture of the incoming concentrate, forming sulphuric acid on the first hearth, and producing a fuming effect. This may account for the increase in the amount of soluble zinc, since experiments have shown that soluble zinc in roasted concentrates can be greatly increased if the raw concentrates are moistened with H_2SO_4 .

LEACHING DIVISION

Leaching is continuous and in two steps: (1) A neutral leach where all the calcine and approximately one-half of the total acid is added; (2) an acid leach where the remainder of the acid is added. Operations may be followed by reference to the flow sheet, Fig. 3. A general plan of the 150-ton leaching building is shown in Fig. 4.

Solution for the neutral leach is made up with one-half the cell-acid (containing 11.5 per cent H_2SO_4 and 7.5 per cent Zn) and the partly spent leach liquor (0.6 per cent H_2SO_4 and 10 per cent Zn) from the acid leach, and run into the first of a series of seven Pachuca

tanks. Sufficient oxidized iron must be present to account for all the arsenic and antimony, otherwise they will not be removed and poor tank-room efficiency will result.

Calcine is fed into the next three Pachuca tanks in such manner that there is an average drop of 2.5 per cent acid in each tank. Nothing is added to the fifth tank, which is used as a control tank in which the acid should be nearly, or completely, spent. One-sixth of the total amount of calcine is added to the sixth Pachuca tank, together with a small amount of limestone. The excess base contained in the calcine and limerock completely precipitates the ferric iron, granulates the gelatinous silica and partly precipitates the copper. These chemical precipitates, together with the insoluble residue, carry down all the freshly formed insoluble compounds of arsenic and antimony. The seventh Pachuca is also a control tank. After the base is added it takes several minutes for the leach to coagulate. This is one of the most important steps in the process; if it is carried out too rapidly poor settling results and in a short time the rest of the plant will be blocked with

FIG. 2. ROASTING HIGH-GRADE CONCENTRATES IN WEDGE FURNACE

mud. When properly carried out each granular particle appears to be inclosed in a flake of freshly precipitated iron, lime or gelatinous silica. The solid particle forms a nucleus for the precipitate and provides the weight to carry down the flaky particles.

The discharge from the last Pachuca goes to the neutral classifiers, which remove the sand for regrinding and return for further treatment. Overflow goes to Dorr settlers, which discharge a clear liquid for the purification process, and a spigot product (50 per cent solids) for feeding the acid leach.

To sum up, in the first, or neutral, leach all calcine enters the process and approximately three-fourths of the soluble zinc is taken into solution; iron is oxidized and precipitated; gelatinous silica is coagulated by excess base and rendered granular; arsenic and antimony are completely precipitated; 80 per cent of the copper is precipitated as hydroxide by the excess base; a large percentage of the zinc is separated from the residues in a clear solution, containing 20 per cent of the soluble copper and all the soluble cadmium.

The ground sand and the settler spigot are leached in three 10 x 20-ft. Pachuca tanks with the remainder of the cell-acid and sent to the acid settlers. It is necessary only that the overflow is maintained at approximately 0.5 per cent acid. Too high acidity interferes with the settlement on the neutral side, increases the volume of solution and causes iron to circulate; too low results in poor recovery.

The spigot product of the acid settlers, containing 60 per cent solids, is filtered, the cake repulped with hot water, and refiltered. Hot wash water is used on each set of Oliver filters. If this double filtering operation is properly carried out, less than 20 per cent of the zinc contained in the residues will be soluble in sulphuric acid. If 90 per cent of the zinc in the calcine was soluble this corresponds to a recovery of 87½ per cent. Fig. 5 is a diagram used in determining the zinc-plant recovery.

Filtrate from the acid filters is combined with the acid settler overflow and goes to copper precipitation tanks, where scrap zinc from the tank room and scrap iron are added to remove most of the copper from the solution.

Summing up, the results of the acid leach are: (1) solution of the remainder of the acid-soluble zinc and copper; (2) final separation of the solids from the zinc-copper solution; (3) roughing out of the copper and chlorine; (4) solution of sufficient iron to guarantee

FIG. 4. GENERAL PLAN OF 150-TON LEACHING BUILDING

the removal of the arsenic and antimony in the neutral leach; (5) elimination of the arsenic and antimony partly redissolved in dilute acid.

PURIFICATION

The overflow from the neutral settlers is pumped to twelve 10 x 20-ft. air-agitated Pachuca tanks, where it is treated, first, with recovered zinc sludge from the purification classifiers to rough out the copper; second, with zinc dust, added carefully until copper cannot be detected by the hydrogen sulphide test; third, with a definite excess of zinc dust to insure that all the cadmium is precipitated. After the addition of the zinc dust, the tank is agitated for fifteen minutes and then discharged through a drag-line classifier to one of two 10 x 50-ft. Dorr settlers in series with six 25 x 60-ft. concrete settling ponds. The pond overflow supplies eight Shriver clarifying presses; the solution after it passes the presses is as clear as crystal, and is ready to feed the tank room.

Failure of the early experimenters to recognize the harmful effects of minute quantities of certain impurities is the principal reason for their disappointment. It is not safe to say that a definite amount of any impurity can be tolerated, because their harmful effects appear to be cumulative. For instance, when a small amount of copper is present (10 mg. per liter), the harmful effects of a little arsenic or antimony are greatly multiplied. Therefore safety lies in the elimination of all to the greatest possible degree. Since purification is based upon the fact that a large excess of zinc dust will completely precipitate the last traces of cadmium and

FIG. 3. FLOW SHEET OF 150-TON PLANT

copper, to get a reasonable degree of efficiency from the zinc a recovery system supplemented by a purification-slime treatment plant is necessary.

Coarse zinc dust from the drag-line classifier is brightened in a pebble mill and reused in purification.

FIG. 5. GRAPHIC REPRESENTATION OF ZINC PLANT RECOVERY FORMULA

Based on the fact that insoluble zinc in calcine equals insoluble zinc in residue.

The sludge from thickeners and ponds is pumped to a scavenger settler, which receives all the spill and washings from the presses and the purification settling system and acts as a combination settler and slime storage tank. The overflow of this settler is pumped back to the purification tanks.

OPERATION OF THE SLIME PURIFICATION PLANT

The spigot product of the last-mentioned settler is pumped to two 10 x 17-ft. Pachucas until they are about one-third full, then cell-acid is run in slowly to dissolve cadmium and zinc and the solution is agitated until the copper just begins to go into solution as noted by the sodium sulphide test. The contents are then pumped to the copper settler, producing a rich slime (30 per cent copper) which is filtered on a 12-ft. Oliver filter and sent to Anaconda for smelting. The settler overflow contains cadmium and zinc; it is run to two Pachucas to which zinc dust is added in sufficient quantity to reduce the cadmium content to that of the neutral Dorr overflow.

These tanks are then discharged into a settler, the overflow being returned to the purification cycle. The spigot product contains 12 per cent cadmium and is stored for subsequent treatment.

ELECTROLYZING DIVISION

The tank house contains 864 cells 10 ft. 3 in. long x 2 ft. 10 in. x 5 ft. deep divided into six groups. Cells are made of wood, lined with lead, and each contains twenty-eight anodes and twenty-seven cathodes. Cathodes are approximately 2 ft. x 3 ft. 6 in. x $\frac{1}{8}$ in. thick, made of rolled sheet aluminum and have a copper contact bar riveted to the top so that 3 ft. of the cathode is submerged. Cathodes are spaced 4 in. centers.

Anodes are made of chemical lead and so cast that the copper contact bar is completely inclosed by the lead except at one end where contact is made with the conductor bar. Anodes have slightly less area than the cathodes and are $\frac{3}{8}$ in. thick. Distance from cathode to anode is therefore approximately 1 $\frac{1}{2}$ in. A triangular conductor bar is used and permits all of the contacts to be on the aisle side of the tank.

Each tank-room unit, or block of 144 cells, is subdivided into twenty-four cascades. Each double cascade forms a stripper unit, which is divided by a runway. Cells of each cascade are placed end to end so that the discharge of the top cells flows into the next lower cells, while the discharge of the sixth cell spills into the tail launder, which carries the spent electrolyte to storage. Solution is fed into the first five cells of a cascade; the sixth is used as a control from which hourly samples are taken and run for acid.

Current for each unit of 144 cells is supplied by a rotary converter of 5,800-kw. output at 580 volts and 10,000 amp. maximum capacity. At full load the current density is approximately 30 amp. per sq.ft. Voltage can be varied 40 volts up or down by means of a booster set. Each additional 1,000 amp. on a circuit calls for approximately 15 volts on the circuit. Figs. 6, 7 and 8 are taken from several valuable diagrams given in the paper which show current characteristics as affected by cell conditions, while Fig. 9 gives the power distribution to the whole plant.

On day shift twelve men strip the metal for each unit of 144 tanks. Nine cathodes are removed at a time and placed in a rack, which permits the stripping of adjacent sides of two plates each time one cathode is swung to the side. The bare aluminum cathodes are washed with hot water and surfaced with a wire brush

FIG. 6. EFFECT OF TEMPERATURE AND ACIDITY ON RESISTANCE OF ELECTROLYTE FOR VARYING CURRENT DENSITIES

FIG. 7. VOLTS PER CELL FOR DIFFERENT CURRENT DENSITIES AND ACIDITIES FOR 2-IN. SPACING OF ELECTRODES AT 34 DEG. C.

when needed. Anodes are cleaned once each month or six weeks. Zinc sheets are not washed before they are sent to the melting furnace.

Every workman in the tank room is furnished daily with a nose and mouth mask of eight thicknesses of antiseptic gauze, to filter out the mist of electrolyte always in the air and caused by gas bubbles leaving the solution and atomizing a small amount of it.

All floors are made of wood, and are insulated from the tanks, bar lines and ground. Steel columns, to the height of a man's head, are boxed with wood. Chain blocks have a strain insulator between them and the crawl. As an added precaution against elec-

tric shock, shoes with non-conducting rubber or wood soles are furnished all men employed in the tank room.

Between 1 and 1.5 oz. (28 to 42 g.) of glue per ton of metal produced, depending upon the amount of impurities in the electrolyte, is added at two-hour intervals. The judicious use of glue gives a dense deposit resulting in better melting recoveries.

Manganese dioxide is deposited at the anode and falls to the bottom of the cell, which is designed with a storage space on the bottom to hold the accumulation for six months, which is the life of the wooden insulators. Originally dry maple blocks dipped in hot paraffine were used to support the conductor bars and dead ends of electrodes; glazed tile has been found preferable where it can be used without crushing.

MELTING DIVISION

The casting plant has two coal-fired melting furnaces with a capacity of from 100 to 125 tons per furnace per day. The firebox is large and deep and is operated as a partial gas producer giving a reducing atmosphere. At intervals the dross is rabbled free of metal with ammonium chloride; once every day it is completely skimmed and further worked while hot in a revolving concrete mixer to which oil and ammonium chloride are

FIG. 8. EFFECT OF VARIATION OF ACIDITY ON POWER COST AT CONSTANT CURRENT DENSITY

FIG. 9. DISTRIBUTION OF POWER TO ELECTROLYTIC ZINC PLANT

added, thus recovering approximately 50 per cent of the zinc.

ZINC DUST PLANT

Approximately 8 per cent of the zinc produced in the tank room is required to precipitate copper and cadmium. The zinc atomizing plant has two units, each consisting of an oil-fired Rockwell furnace, two blowing nozzles, and a settling chamber with a superimposed bag house. Air from the nozzles strikes a small hot stream of metal at right angles, atomizing it and blowing it into the settling chamber.

RESIDUE TREATMENT

The wet residue from the Oliver filters is dried in two 7 x 50-ft. Ruggles-Coles driers and three 9 x 60-ft. horizontal, single tube, rotary driers (moisture is thus reduced from 25 to 7 per cent) and then conveyed to storage

bins in 50-ton dump cars. Three 300-ton bins are used for dried residue, and one each for fine coal, siliceous ore, copper concentrate, lime rock and circulating material such as converter slag and cleanings. Each compartment discharges through a measuring chute to a belt conveyor which in turn discharges in a storage bin, supplying feed for reverberatory furnaces, and taken there by cars via local tramming system.

Furnaces are 125 ft. long x 22 ft. wide x 8 ft. high, measured from the silica bottom to the under side of the arch at about mid-length, originally built to smelt copper calcine but remodeled by lowering the bottom 2 ft., and by increasing the size of flues so as to permit as much lead fume to settle here as possible. Flue cleanings are shipped to the Tooele lead smelter for treatment. Slag is skimmed twice a shift, and stored, since it is planned to re-treat it to cover its zinc content (11 per cent Zn, 30 per cent FeO, 27 per cent SiO₂, 16 per cent CaO).

RECOVERY OF LEAD

Matte is overblown, before adding any siliceous flux, so as to expel as much of the lead as possible as volatile compounds, and the fumes are collected by flue leading to a bag house.

Fume-laden gases from the reverberatories are conducted through an 8 x 10-ft. flue to four Stirling waste-heat boilers, and thence through a 10-ft. hopper-bottomed steel flue, 1,200 ft. long, to the cooler pipes and bag house. There are thirty cooling pipes, 30 in. in diameter by 120 ft. long, arranged in parallel. Each pipe is in the shape of an inverted U and is equipped with a butterfly damper for velocity control. Whenever radiation will not cool the gases to 90 deg. C., cold air is drawn in through special doors located between the cooler pipes and the fans, which latter provide draft for the furnace and pressure for the bags. Pressure is normally about 1 in. of water. Originally the bag house contained eleven sections of 138 bags, each 18 in. x 30 ft. (45 cm. x 9 m.); in 1918 six sections were added to provide additional capacity for matte conversion. There is a cross-connection between the suction flue to the coolers and the distributor flue to the sections so that when the dampers are opened in the cross flue, a back draft results and the bags are collapsed, freeing most of the dust, and the exhaust gas from the section is forced into the bags of the other sections. However, the bags must also be shaken by hand at intervals, otherwise the fabric pores will gradually be filled. Dust is removed by screw conveyor to standard gage railway cars for shipment to lead smelters.

Thus, the object of the residue treatment is to collect the maximum amount of copper, gold and silver in a leady matte with a minimum amount of zinc, and to slag as much zinc as possible while making a fume rich enough in lead to ship as a lead product. Over a period of six months when smelting a residue of the approximate analysis 15 per cent lead, 13 per cent zinc, 2 per cent copper, 23 oz. silver and 0.07 oz. of gold per ton, 12 per cent silica, 29 per cent iron oxide, the recoveries were: copper 90.78 per cent, gold 74.05 per cent; silver 93.04 per cent; lead 72.65 per cent.

New Bamboo-Paper Pulp Plant

It is learned from Vice-Consul Thorling that a big bamboo-paper pulp plant is to be opened in the Pegu District, Burma, by F. W. Heilger & Co., managing agents for the Titaghur Paper Mills Co. (Ltd.).

Book Paper From Southern Pine*

Book paper requires for its manufacture two kinds of woods—a long-fibered wood, such as spruce, to impart strength, and some short-fibered hardwood to give the formation, finish, opacity and other printing qualities. The Southern pines are long-fibered woods, excellently suited for the manufacture of wrapping paper and fiber board, but their pitch content and the difficulty of bleaching them have heretofore been obstacles in the way of their use for white paper. These obstacles, it has been shown, can be overcome in a large measure by proper cooking conditions and improved bleaching methods. Red gum is typical of many Southern hardwoods that might be used with the pines in the manufacture of the better grades of printing paper.

The laboratory experiments indicate that one cord each of loblolly pine and red gum are capable of yielding one ton of paper, at a cost which should allow a good profit under prevailing conditions.

The utilization of the Southern pines for book paper would spread the burden of the pulpwood supply over considerable territory which is favored with a large annual growth of timber. In fact, although the bulk of the standing timber of the United States is in the far West, the bulk of the annual growth is now in the South. Pines and hardwoods are distributed throughout the Southern States in proportions well suited for the manufacture of book papers, and the forests are near the centers of paper consumption as well as the supplies of coal, chemicals and other necessary raw materials.

Margarine Industry of Hull, England

In addition to being one of the most important British centers for the treatment of oilseeds and the production of various oils, paints and colors, Hull is rapidly gaining a commanding position in the matter of the production of oleomargarine. This is practically a new industry for the district, reports Consul John H. Grout of Hull, England.

About four years ago the manufacture of compound lard was commenced, and this lard has now reached a degree of popularity that is securing for it universal use. It is generally admitted to have superseded hog lard in this district. The manufacture of margarine at Hull is a more recent development. Among the different brands produced are those intended for table use, for cake making and for pastry.

Annual production figures covering the margarine industry of the Hull consular district are at present very difficult to obtain. However, in 1915 the weekly average production of margarine in all England amounted to 2,200 tons, which was followed in 1916 by a weekly output of 2,500 tons. In 1917 the total had increased to 3,500 tons per week. In 1919 the industry made great advances, owing to the opening of new works throughout the country; the weekly production for January of that year averaged 7,500 tons, in February 6,200 tons, in March 6,400 tons, in April 6,350 tons, in May 8,500 tons, in June 6,000 tons, in July 6,000 tons, in August 4,800 tons, in September 6,350 tons, in October 5,950 tons, in November 7,500 tons and in December 5,220 tons.

From such information as is obtainable it would appear that for the year 1920 the average weekly production was in the vicinity of 7,000 tons.

*From *Technical Notes*, Forest Products Laboratory.

Pulverized Coal

ALTHOUGH experiments in the use of pulverized coal were begun nearly a century ago, the first practical application of the use of the fuel in powdered form was not made until about 1895. The cement industry, disturbed by the increasing cost of oil, sought for a low-priced fuel of high efficiency. Their plants were equipped, also, with the machinery necessary to reduce to powder cement rock or clinker and the pulverization of the less resistant fuel presented no difficulties. A series of experiments, begun in 1894, resulted in the following year in the installation of a practicable device for burning powdered coal. Its use has never been discontinued and at the present time 90 per cent of the portland cement made in the United States is burned by means of powdered coal.

Experiments with the new type of fuel were undertaken in other industries from time to time during the next fifteen years, but it is only within the last decade that the consumption of powdered coal in the United States has grown to any considerable proportions. During the calendar year 1919 it is estimated that between 10,000,000 and 12,000,000 tons of coal was pulverized for industrial consumption. Of this amount 6,000,000 tons was consumed in the making of portland cement; 2,000,000 tons was used in the iron and steel industry; copper refining consumed 1,500,000 tons, while at least 250,000 tons was used in power plants. The remaining consumption of pulverized fuel was divided among a large variety of industrial uses.

INCREASED USE OF THIS FORM OF FUEL

A better understanding of the principles involved, together with improvements in furnace design, has overcome most of the difficulties encountered in the earlier experiments, many of which were nothing more than attempts to burn pulverized coal in furnaces intended for other methods of firing. Further study of various grades of coal with a view to their suitability for use in pulverized form, as well as the design of improved machinery for reducing coal to the necessary degree of fineness, has also contributed largely to the increased use of this form of fuel. The use of pulverized coal on a large scale has been tried in Great Britain only in the cement industry, but the urgent necessity for the conservation of fuel supplies in that country is directing attention toward it as a possible means of economy. Apparatus for burning pulverized coal has been installed also in France and Japan, while Italy has recently sent a commission of engineering experts to the United States to investigate the subject.

ECONOMIC ADVANTAGES

The fundamental economic advantage in burning pulverized coal lies in the complete stage to which combustion is carried in the furnace. The contact surface between coal and air is greatly increased by splitting the coal into numerous particles of small size. A 1-in. cube has an exposed surface of only 6 sq.in., while the same volume divided into a thousand cubes of 0.1 in. has an exposed area of 60 sq.in., and if the division be carried to one million cubes 0.01 in. on a side, the exposed area in which combustion takes place is increased to 600 sq.in.

The second advantage in the pulverization of solid fuel is the fact that it floats in the air, spreads and is carried off by even small air currents. This makes the

intimate mixture of coal and air very easy. It simplifies the construction of burners and guarantees economical combustion. The finer the coal is powdered the more nearly ideal conditions for complete combustion are approached.

Where proper apparatus and methods are in use, however, other more tangible economies are effected by the use of powdered fuel. The labor cost of firing is materially lowered and losses during short periods when steam pressure is not required are reduced to a minimum. No air is allowed to pass through the furnace when firing operations stop, so that the radiant heat of the furnace is absorbed by the boiler, avoiding the losses which occur with grates or stokers through the constant burning up of fuel and incomplete combustion of the gases generated from banked fires. The time necessary to get up steam is reduced by half when pulverized coal is substituted for the same fuel in lump form. Recent experiments also show an economy in fuel consumption, which in some instances is said to be as high as 30 per cent.

LOW-GRADE COALS NOW UTILIZED

Until very recently the impression has prevailed that only certain grades of bituminous coal were suitable for powdering. Early experiments in the use of low-grade coal were nearly all failures, but as the conditions necessary for practical operation have become more thoroughly understood the low-grade coals have been utilized successfully. All the most recent developments in the use of powdered coal as a fuel for steam-generating plants have been made with anthracite culm, at one time definitely abandoned as a fuel suitable for powdering. High volatile soft coal gives best results, but mixtures of such a grade of coal with anthracite culm have proved entirely satisfactory and pulverization may be applied to any solid fuel, peat, lignite or bituminous coals of any grade, as well as anthracite and coke. All of these fuels are burnt successfully in powdered form, because the inherent advantages of exact regulation of air and combustible matter, with a proper mixture of both, may be secured. Higher temperatures than are possible with lump fuel can be maintained in furnaces fired by powdered coal because the quantity of excess air is only about 20 per cent compared with an excess of from 50 to 200 per cent with hand or stoker fired coal.

METHOD OF POWDERING

In the preparation of coal for use in the powdered condition the first operation is a crushing to lumps about one inch in size. Following the crushing the coal should be dried down, if possible, to less than 1 per cent of moisture. The crushed coal is then passed through a magnetic separator, which removes bits of steel or iron that would interfere with pulverization. Drying is desirable both for proper pulverization and to make the fuel burn freely. The coal is dried by being passed through a revolving shell, the temperature of which is maintained at a point high enough to cause the vaporization of practically all the moisture contained in the crushed fuel.

After being dried, the coal is pulverized to its final degree of fineness, such that 85 to 90 per cent will pass through an aperture $\frac{1}{100}$ in. square. The powdered fuel is conveyed directly from the pulverizing plant to the furnaces, either by a system of screw conveyors or by air pressure. It is fed to the burners through a nozzle under light air pressure.

An Engineer Who Anticipated Hoover

BY P. B. McDONALD

Assistant Professor of English, College of Engineering,
New York University

WHILE Herbert Hoover stands pre-eminent today as the type of American who won high success abroad by applying science and economics to foreign problems in a characteristically American way, he should not be thought the first of that type. To a certain extent Benjamin Franklin anticipated him by over a century, and astonished Europe by his shrewd ability and use of scientific methods. But there was another American, contemporary in part with Franklin, who won striking success in Europe but whose remarkable accomplishments are little known. This was Benjamin Thompson of Woburn, Mass., later Sir Benjamin Thompson and Count Rumford of the Holy Roman Empire, to whom England owes its Royal Institution and to whom Bavaria erected a splendid bronze statue, later duplicated at Woburn.

Benjamin Thompson was a scientist and administrator. He proved that heat is a mode of motion, not a fluid substance as it was then thought, and he determined within 10 per cent the dynamic equivalent of heat, later corrected by Joule. Since Thompson, or Rumford as he perhaps should be called, anticipated Joule by forty-two years, Dr. E. E. Slosson is justified in suggesting that the unit called the joule might better have been called the rumford. (See Slosson's essay on Rumford in "Leading American Men of Science," edited by David Starr Jordan.) But, like most practical Americans, Rumford believed in applying his knowledge of science. He improved the design of fireplaces, founded the science of interior ballistics by experiments with cannon and gunpowder, anticipated the "fireless cooker" of today, helped solve the question of the best covering for steam-pipes by observations on radiation, gave the world much-needed suggestions about clothing, contributed to the development of knowledge about lamps, colors, meteorology, the three ways in which heat travels, etc.

FOUNDED THE ROYAL INSTITUTION

As an organizer and administrator, he reformed the Bavarian army, housed the beggars of Munich and put them at useful work, and got a number of the leading men of England to contribute to the Royal Institution which he founded. This institution has done more for the advancement of science than probably any university in the world. Among its famous workers have been Davy, Faraday and Tyndall, and today it remains an active influence for research, housed in a palatial building in London. Other evidences of the foresight of this Yankee Count survive in the Rumford professorship which he founded at Harvard, and in the Rumford medal of the Royal Society of London and the Rumford medal of the American Academy of Arts and Sciences. When Rumford died near Paris in 1814, the great Baron Cuvier eulogized him before the French Institute.

But this distinguished scientist and administrator did not have things all his own way, as a record of his accomplishments might indicate. Though his family had lived in America for over a century, he left this country at the outbreak of the Revolution and fought against the colonies as a British officer. This was after he had offered his services as a brilliant young man to Washington and been refused because his enemies were

jealous of his rapidly increasing eminence. In England he found instant recognition and was made cavalry Colonel and Under Secretary of State while yet in his twenties. After the Revolution, he made the acquaintance of the Elector Palatine of Bavaria by his fine appearance on horseback, and was offered exceptional honors to stay in Munich and devote his talents to the government there. In Bavaria he became Count, Privy Councilor, Minister of War, Chief of Police, and Chamberlain to the Elector Palatine.

A PERSONALITY THAT THRIVES IN A MONARCHY

In person, Rumford had excellent manners and a ready flow of language, but he was opinionated, obstinate and disposed to have his own way, especially about little things, such as concerned his theories of clothing, cooking and household management. His unusual personality was the kind that prospers more in a monarchy than in America, because aristocracies make more allowance for eccentric geniuses than do democracies. If he had remained all his life in the land of his birth, he likely would never have risen higher than some petty job at the beck of a captain of industry. In England the Colonial Secretary of State, after one interview, recognized the ability of the young New Englander and gave him a place in the Colonial Office, making him a member of his own household. Later in Bavaria the Prince Maximilian spoke to him and invited him to dine because he liked his handsome appearance at a military parade where Rumford was a spectator. Directly afterward he was introduced at the court in Munich and was offered inducements to stay there in official capacity.

It is evident that, besides resembling Hoover in attainments in applied science and organization, he was like him also in rising from a poor American boy to an associate of kings and a great philanthropist. Hoover, however, has found honor in his own country while yet a comparatively young man, whereas Rumford has never been well known by Americans, and was even reviled as a traitor for many years until a more tolerant attitude grew up toward the Loyalists. Possibly Hoover would have become a great engineer if he had remained in America, instead of seeking his fortune in Asia and Europe; as to that, however, it is impossible to decide, for if he had never left this country his life would have been widely different. America offers prosperity to men of a certain pushful and businesslike bent, but does not confer favors on so wide a range of talents as do the older civilizations where life is more diversified and success is less standardized. Probably, just as there are Europeans who succeed better in America than in Europe, so there are particular types of Americans better adapted to succeed in Europe than in America. Such an interchange is beneficial to both continents, since it makes for distribution of ideas, and adds to the variety of minds available to help solve the problems of any one country.

Correction

In the article on "Comparison of Various Methods of Water Purification," by William Macklin Taylor, published in the Jan. 19, 1921, issue of CHEMICAL & METALLURGICAL ENGINEERING there was a typographical error. In the table on page 124 the hardness of water treated through a zeolite water softener, calculated to calcium carbonate, was given as 6.50 grains per gallon. This should have been 0.50 grain per gallon.

Costs—A Short Study of Factory Economics*

A Manager's Point of View of the Functions of and Services to Be Received From Factory Cost Departments — Factors of Interdependence of Costs — Maximum Net Returns on Groups — Distribution of Ledger Totals—Forms for Recording Operations—Statistics, Reports and Item Analyses

By A. G. PETERKIN

THE layman's idea of a cost system is a mechanical routine which month by month turns over to the sales department the cost of each of the materials which it sells. As a matter of fact, it has been attempted in many cases to put this idea into operation. I think it is true that the result has been a compilation of figures which fall under the head of "statistics" in Walter Bagehot's famous expression: "There are lies, damn lies and statistics." The problem which confronts the manager of a factory is not the mechanical grinding out of so-called cost figures, but a study in economics.

WHAT SHOULD A COST SYSTEM DO?

In the first place, a cost system should give information to the sales department which will enable its members if possible to sell the production at a profit. The sales department, however, is not able to control the market price of certain commodities, which are set by outside conditions and the selling price of other commodities. For example, if a substitute material is offered, the limitation is imposed that the selling price must have some definite relation to the price of the material substituted. In such cases, given a process of manufacture, the cost system is required to tell the price at which the raw materials must be bought to enable the material to be marketed.

It is of no less importance that the system should tell the factory management and the sales department under just what conditions the costs submitted are possible, and in what way they will be affected by changes in method of manufacture, and by increase in the individual or total volume of production.

The cost system might be required to produce a sense of financial responsibility in the heads of all the various departments, from the top down. This is particularly true of corporations or large businesses where the combination expected to give results is that of "your brains and someone else's money." The repair department, for instance, should be run as far as it is possible in the same way as a separate business which was furnishing the same service to the plant. The head of every production department will, to my mind, work to better efficiency when it is required of him that he think in terms of dollars and cents as well as in terms of men, pounds and gallons; he should run his department in the same spirit as he would were he using his own money. So far as possible, every man should be required to know how much money he is spending for every item where the discretion he uses in his daily work will influence that item.

When once reliable cost figures have been established and analyzed, it is more important to obtain information looking toward the control of the expenditures making

up the cost than to repeat the calculation of the final figures at frequent intervals to the exclusion of such information. The one method leads to irritating post mortems; the other avoids them. As in sport, so in business, watch your stroke, and let the score take care of itself.

INTERDEPENDENCE OF COSTS

In setting out to arrive at such results at least one simple principle must be kept in mind. When once a factory has been organized to turn out any given set of products, so far as cost is concerned every one of those products becomes to some extent interdependent. To get a definite cost figure on any one of them, the cost of each one of the others must be fixed at the same time. The more varied and complex the operations of the plant are the truer this is. It is least true in a factory, if such a one exists, where each one of the products is independent of the others so far as labor, raw materials and intermediate materials are concerned. In such a case as that, the interdependence lies mainly in the overhead, and the variation in cost will arise from the difference from time to time in what may be called the degree of saturation of the overhead. When the volume of production which a given organization can turn out is the maximum, the costs will be lowest, and as the volume decreases the cost of each one of the different materials will go up.

This factor of interdependence, however, in the chemical business is influenced much more by another condition than by overhead expense: If the decision is made to manufacture a certain material by a chemical process, one is almost always confronted by the necessity of producing another or even several others simultaneously. These "byproducts" may or may not be useful and valuable. The growth of the industry has largely been effected by making them so. The two or more products from such a process may have been subjected to exactly the same procedure and no more expense incurred in making one marketable than any of the others; on the other hand one or more of the products may have necessitated a disproportionate expense. Does this extra expense as an item of cost belong to the products directly responsible; or should the total expense be divided equally among the group? Assume for a moment that the expense is allotted as directly as possible among such a group of complementary materials and costs figured on this basis are given to the sales department. What naturally happens? Vigorous selling of the profitable members and an accumulation of the less profitable! Finally of course all have to be disposed of and the net result is a profit or loss on the group. The only rational basis for computing costs, and profit, is on the group considered as a unit. No arbitrary fixing of values within such a group changes the basic fact that the profit is made on the sale of the

*Read before the American Institute of Chemical Engineers, New Orleans, Dec. 6, 1920.

entire production, although the use of such values may in some cases be a convenient and good method of studying the group profit. Such arbitrary values placed on certain members may not materially affect the cost of the other members, either in amount, in variation or in both. For example, in the manufacture of nitro products, with the attendant production of "spent acid," to figure a cost and profit on the group would merely tend toward confusion. The market value of the "spent acid" can be ascertained with considerable ease; the

of the price at which a finished product from one process shall be charged as a crude to another. If such a material be marketable in the maximum volume possible to produce, it might well go into the subsequent process at its market price, since the only justification for the expense of further fabrication is a profit greater than can be obtained by its sale. The first process must then be given the credit for the profit which would have accrued had the sale taken place. If the object of further processing is to take care of an otherwise unmarketable excess, the same reasoning would lead to its being charged in as a crude at not more than actual cost.

Before going into the details of the actual work of a cost department, the relation between the bookkeeping and the cost systems should be clear. Fig. 1 shows the layout of the former; Fig. 2, that of the latter.

DISTRIBUTION OF LEDGER TOTALS

The cost system is not an essential part of the bookkeeping system; it is an analysis of the bulk cost of the operations carried out; it does not even furnish, necessarily, the value of each item of the inventory. Of course, in possibly the majority of cases, the individual inventory items are placed on the books at a value figured out by means of a more or less mechanical system, but exceptions always have to be made where such a value bears no relation to the actual market value of the material. It is an unfortunate fact that occasionally materials are manufactured at a cost which is greater than the market value, and the inventory based on such a cost would certainly be inflated by at least the difference between the two values.

To go now to the methods to be employed in compiling plant statistics, and to the finished form they shall take:

The direct charges to any product or group of products, for superintendence, labor, repair, materials, etc.,

placing upon it of such a value will throw all the cost and all the profit to the nitro product, and will clearly give the information necessary to a proper manufacturing and sales policy.

MAXIMUM NET RETURNS ON GROUP OF PRODUCTS

Possibly the best example of this phase of the subject is the case of a factory refining oils. Each crude worked may give some amounts of the same materials and at the same time products peculiar to itself. Each crude, also, can probably be worked up in various ways to produce several sets of products. The attempt to follow each intermediate step in the refining process, to find the cost of the intermediate products and so on to the finished products, results in figures which are valueless in most cases. The question here is of the proper profit on the group of products from one crude, and the most profitable group to make from that crude. Frequently every finished product has an established market price, and the price which can be paid for the crude has to be determined by taking the difference between the combined market value of the entire production, and the total working cost, freight, profit, etc.

There are many cases where evaluation of individuals is necessary in which the products cannot be evaluated by placing arbitrary values on the minor members, and dividing the remainder of the cost proportionately. A rule capable of fairly general application is to divide this remainder among the major products in the proportion of their market values. The one point which should never be lost sight of, however, is that the manufacturing and selling policy should be governed by the net return on the group.

Another phase of the same problem is the question

are calculated by distributing the ledger totals for these items by means of the usual code system, using report blanks for record of labor-hours, etc., placed in the hands of the foremen or workmen as may be judged best.

The question of the method to be used in assigning indirect charges, superintendence and various expenses covering several departments, the plant burden, etc., is a vexed one. So far as possible, each one of the items going into any such general expense account should be spread over the products necessitating it on a logical basis applying to the individual item alone. The cost of the control laboratory, for example, can as a rule be split up and charged to the products involved, on the basis of the actual cost of the tests made for each one. Such few items as cannot be treated in this way—for example, office expense or general management—have necessarily to be grouped together and prorated on an arbitrary basis. The basis most generally used is that of "productive" labor; the products are charged with their quota of expense calculated from their proportion of the direct labor in the plant. Such a general method, of course, cannot give even an approximation of the truth, unless the labor entailed in each of the group of processes employed in the plant depends on the volume of production rather than the kind. It is obviously true that some processes requiring but little labor consume an altogether disproportionate amount of the expense of superintendence, development, etc. The "punishment must be made to fit the crime," and no rule for such prorating of overhead capable of general application can be laid down.

In general, I believe it is true that yield is the most important item of cost in the chemical industry. The first essential, therefore, in any "chemical" cost system is the obtaining from the factory of accurate figures representing the operations carried out. For that reason I shall go in detail into one method which attempts to do this in a manner which leaves no figures to the imagination.

In order to follow the path of raw materials through a process all the way from the purchase of the crudes to the output of the refined materials, it is necessary to check the weight, or volume, or both, as it is received into the plant; to check the losses or discrepancies caused by errors of measurement as it passes from one part of the plant to another and into the actual apparatus where the process is carried out; to record the amounts of materials produced, both in intermediate stages and in the containers on the railroad ready for shipment to the customers; and to record the amounts of materials in process and in stock at the inventory period. It is important that the means employed to do this should enable one to detect physical losses at the time they occur.

Form 1 of the accompanying diagram is a receiving report which is so arranged that the amount of material arriving in any kind of package can be recorded as compared with the actual amount received into the storage.

Form 2 is a continuous inventory card, by means of which the individual foreman keeps a record of each lot of each material placed under his supervision. On it he records every movement in or out of the tank, bin,

to record at monthly intervals the amount of material in the apparatus at the end of the month, so that the production corresponding to the charge for the period can be calculated.

Form 5 shows a form arranged for record of transfer of material from one part of the plant to another, where such material is not going through a process, and enabling a record of discrepancies between delivered and received amounts.

Form 6 contains a complete list of all apparatus under the charge of each process foreman, on which to record the material charged to the apparatus, the production from which is incomplete at the time of the inventory.

Form 7 is used to determine the inventory of each material in the plant at the end of the month, or at the end of whatever the cost accounting period may be. The figures on this inventory card are posted from the running inventory cards kept by the foreman.

From these reports, properly checked and recapitulated, a complete ledger statement can be made up, which, if the records have been accurately kept and carefully checked, should give an exact balance. Inasmuch as every amount of material moved has been recorded on one or the other of these forms, and the movement checked by the cost department, there is no possibility except through human fallibility (that troublesome factor in all "systems") of any quantity of material not being on the cost department records.

Let us turn now to the consideration of the statistics which should be obtained from a cost department to control properly the operations in a chemical factory.

The manner in which the figures are presented, if they are to be used, is important. First, no matter whether one is studying the whole plant or any particular part of the plant, one should go from the top down. The first figures examined should represent a summary of the expense of the operations under examination; they should omit detail and present a birdseye view. It is not difficult to remember, say, twelve items going to make up a total, nor to understand and remember the relation between twelve such figures. If it is attempted to study a total comprising 144 items, the average mind merely becomes confused, arrives at no decision, and no picture of the operations represented by the figures remains. Condense the 144 figures, however, into twelve sub-totals, the relations between these are easily grasped and they furnish a definite picture. Analyze each one of the twelve items further into twelve more, and each of the subdivisions becomes clearer and more intelligible as its detail is studied. The twelve principal subdivisions then become mental pegs on which to hang the remaining 132 of the figures in easily comprehended groups. Skillful summarization is the secret of useful statements. Diffuseness is the curse of cost accounting.

The total list of reports submitted, each covering

monthly or longer intervals, might be somewhat as follows:

1. Complete balance sheet showing all the money spent during the month, and the main departments where the expense was incurred.
2. Analysis of profit.
3. Analysis of the total cost of all production under a few headings of direct expense.
4. The volume of production from, and cost of the working of individual processes or crudes. (The form of this report should be particularly noted. It does not provide for the computation of the costs of intermediate materials; these are supposed to be estimated by the technical staff. By estimating the value in finished products of the intermediates used and produced, the yield on the entire process can be calculated. The attempt to get a cost on each operation of a process is usually more expensive than the results are valuable.)
5. Analysis of the plant expense.
6. Analysis of cost of repairs.
7. A detailed statement of sales, giving volume and value for each commodity. This form is not illustrated.

COST ANALYSIS

These, together with a more or less detailed analysis of each, should constitute the bulk of the cost department's work. Much attention should be paid to the arrangement of data on the books so as to facilitate the preparation of such analyses as may be necessary from time to time to explain unusual fluctuations. It is much better to submit comparatively few summaries and to be prepared to furnish analyses of any of them quickly than to attempt the regular periodic compilation of many detailed statements.

The statement "Analysis of Repairs" is an example of a report gotten out upon request to explain an unusually large repair charge. That headed "Weekly Report of Construction" is a report for the use of the engineer on a construction job, which enables him to compare the amount of money spent to date on his work and the money appropriated to complete it. The "Laboratory Cost Sheet" is a monthly report to the chief chemist who may well be required to work under a budget; it includes all the expenditures for which he is responsible.

In presenting cost figures to the sales department month by month, one very general condition experienced is fluctuations in cost, due to the fact that repairs and other expenses are not incurred equally month by month. It is sometimes attempted to equalize such expenses by setting up on the books deferred charges, so that a very heavy expense is not charged to the operations going on in the month wherein the expense was incurred, but is spread over a period of several months, or even a year. Such a method as this leaves so much to the judgment as almost always to lead to confusion, and possibly also to embarrassment; no one likes to have deferred charges on his books. In my opinion, the better way is to charge all such expense to the operations when incurred, and to flatten out the cost figures by averaging them over periods of say six to twelve months. This would mean that in January the cost submitted would be the average of the past six months of the old year and the first one of the new, and so on until the end of the first six months of the year is reached, when the cost may become cumulative from the first to the end of the year.

The money spent on costs covering the ground indicated here need not exceed 0.5 per cent of the payroll; the difference between good management and the best possible is, I should guess, about 10 per cent. The one almost universal trouble experienced with cost departments and systems is their tendency to spend more

money on statistics than the use of the figures they submit can possibly save. Coupled with this is the tendency to attempt to turn out mechanically, month by month, large volumes of significant figures. The number of figures which a cost department is asked to produce each month should be cut down to the very minimum, and these should be only such as can be turned out by a mechanical routine and wherein as few elements of judgment enter as possible. Analysis beyond this point should be done by the technical staff of the plant, or by a department of cost analysis run, not by bookkeepers, but by men whose judgment is based on a real, solid understanding of the processes. The fewer and more simple the figures which the ordinary cost department run by bookkeepers and clerks with no operating experience and the greater the insistence that the technical staff of the plant take the figures, analyze and interpret them the more likely it is that valuable results will be obtained. An adding machine cannot think. It will say, for example, that a certain product is unprofitable; its manufacture, therefore, is discontinued. To your surprise, however, instead of saving the loss, a still greater loss is incurred. Shutting down the plant has not decreased outgo as much as it has decreased income. Depreciation, insurance, taxes, still continue; the plant begins to deteriorate and assets to drop; the overhead allotted to the plant cannot all be cut out and has to be carried by other processes. In general, the only safe way to determine whether a production shall be discontinued, increased or diminished is to disregard the individual cost figure, and to sit down and figure the effect the proposed change will have on the total income of the plant on the one hand and the total outgo on the other. Not until that is done can one be in a position to say whether the proposed change will result in greater profit, or in the least possible loss.

CHEMISTS AND ENGINEERS OUGHT TO BE FAMILIAR WITH ACCOUNTING METHODS

In the Philadelphia *Public Ledger* of Feb. 18, 1918, a statement was made in one of the editorials that 95 per cent of the businessmen of Germany are expert accountants. The continual association of values with materials and effort is an essential in the education of a successful chemical engineer. Of necessity it is omitted from his college training. The opportunity for doing it should be freely given in the industries.

The chemists and engineers in charge of our factories must be familiar with accounting methods. The economics of the factory must come within the scope of their activities. They must be able to use the help of the accountant. The officials of a corporation must be able to rely upon their technical men for sound advice, not only in the realms of physics and chemistry, but in economics also. Webster says that "economics is the art of regulating receipts and expenditures so as to insure a proper profit." Surely this is an art we need to acquire and not leave to a bookkeeping department.

What Otto Witt said in 1887 is truer than ever today: "The success of a process is no longer, as formerly, dependent upon the careful preservation of manufacturing secrets, but above all upon businesslike control, both within and without."

Chemical Department,
The Barrett Company,
Frankford, Philadelphia, Pa.

Development of the German Chemical Industry During 1919

A recently published report on the German chemical industry for the year 1919 contains some interesting data concerning the development of this important branch of industry.

The following figures show the number of plants in operation during 1919, and number of workmen employed:

District	Number of Plants	Number of Workmen, Full-time and Part-time	Decrease in Number of Full-time Workmen From Preceding Year, Per Cent
Berlin.....	2,518	68,393	7.31
Breslau.....	1,235	26,377	20.84
Hamburg.....	2,043	72,859	27.89
Cologne.....	2,562	121,537	31.85
Leipzig.....	2,648	125,559	12.04
Mannheim.....	1,325	50,615	12.80
Frankfort.....	1,081	51,198	2.70
Nuremberg.....	1,648	27,623	13.35
Total.....	15,060	544,161	18.18

From these figures it appears that the greater part of Germany's chemical plants are located in the Leipzig, Cologne, Berlin and Hamburg districts. There were 15,204 plants in operation in 1918, while the total had fallen to 15,060 in 1919, a decrease of 1.95 per cent. This decrease is due chiefly to the fact that the chemical plants in Alsace-Lorraine were eliminated from consideration in 1919. The number of working days credited to the 294,766 full-time workmen reached a total of 88,231,447 against 107,835,679 for 1918.

WAGES PAID AND NUMBER OF PLANTS IN OPERATION

The total amount of wages earned by workmen and employees in the chemical industry in 1919 amounted to 1,131,682,109 marks. If one uses as the basis of comparison the number of plants in operation, the number of full-time workmen, the wages earned, together with the annual compensation received, the figures for the single years during the period 1913 to 1919 show a generally upward trend.

Year	Number of Plants	Number of Full-time Workmen	Total Amount Wages Paid, Marks	Average Annual Compensation of Full-time Workman, Marks
1913.....	15,042	227,629	351,520,206	1,266
1914.....	15,014	245,980	313,508,108	1,273
1915.....	14,914	219,646	295,217,251	1,344
1916.....	14,998	256,420	382,783,261	1,493
1917.....	15,129	334,851	652,877,501	1,950
1918.....	15,204	360,256	889,141,025	2,468
1919.....	15,060	294,766	1,064,782,786	3,612

A slight decrease is to be observed in the number of plants in operation during the period 1914 to 1916. In 1917 the number of plants was larger than for the year 1913, and the increase continued in 1918. In 1919, however, there occurred the slight decrease previously noted. The number of full-time workmen employed in 1919 exceeded by 17,000 the number employed in 1913. The year 1918, with its total of 360,256, marks the high-water point in full-time workmen employed.

It is interesting to observe that compared with 1913 the amount of wages received in 1919 has tripled. The highest point in the total wages paid was reached in 1919. Hand in hand with this growth went the increase in the average annual compensation of the full-time workman. In 1913 this figure amounted to 1,266 marks, while in 1919 it had risen to 3,612 marks. Everything points to a heavy increase in the 1920 average against that of 1919. In the course of the present year workmen in the chemical industry have been paid such amounts as would indicate that the average annual wage might reach a total of 18,000 marks or even more.

Pulp and Paper Production in Quebec, Canada, During 1919

The total quantity of lumber cut in the province was 814,455,900 ft. b.m., as compared with 931,462,800 ft. in 1918. In 1919 there were sixteen pulp mills in Quebec Province, with an aggregate daily production of 1,300 tons, and twenty-seven combined pulp and paper mills producing 1,600 tons of paper daily. A conservative estimate gives the year's production of pulp of all kinds as 800,000 tons and of paper and paper products as 450,000 tons, the greater part of the pulp being consumed in the manufacture of paper within the province. The selling value of the entire output was \$65,000,000, an increase of \$13,294,217 over the figures of 1918 and of approximately \$23,000,000 over those of 1917. Most of the products are sold in the U. S.

Reconstructing French Chemical Industry

France has made notable progress in setting her chemical industry on its feet again. The 17 per cent of the chemical plants of all kinds in France which were located in the devastated departments were almost entirely destroyed. The departments of the Nord and of the Aisne suffered particularly, supporting 70 per cent of the total damage, which is estimated according to 1914 values to be 128,840,208 francs.

The Ministry of Liberated Regions, which has taken a census of the various plants that can be classed under the heading "chemical industry," announces that on Oct. 1, 1920, 111 out of 142, or 78.1 per cent, had resumed operation wholly or in part. The greatest proportion in resumption of operation is found in the Lille region (89.3 per cent). These 142 plants in 1914 employed 21,210 workmen. On Oct. 1, 1920, 54.2 per cent of this number, or 11,512, were employed in production. The nearest approach to normal is found in the Department of the Meurthe et Moselle. A year ago, or on Oct. 1, 1919, only 18.7 per cent of the 1914 personnel was occupied at production. Since that date there has been a steady increase, the proportion from Jan. 1, 1920, increasing from 34.7 per cent to 54.2 per cent above mentioned.

The production in 1914 of the plants which can be classed under the heading chemical industry proper was estimated at 850,000 tons. The present production is between 200,000 and 300,000 tons. Under this heading are included plants manufacturing sulphuric acid, nitric acid, hydrochloric acid, sodium sulphates, iron, copper, sulphites, superphosphates, ammonium salts and various fertilizers. No figures are yet available on the production of chemical byproduct factories, either for 1914 or at present. Under this heading are classed all factories which handle chemical products already prepared, such as salt refineries, the preparation of sodium crystals, hypochlorites, pharmaceutical and hygienic products, photographic materials, etc.

The chemical industry in general throughout France has received great encouragement as a result of the war. Prior to 1914 the industry was of relatively minor importance, French manufacturers preferring to import the necessary supplies from Germany, which for years had specialized in this branch of industry. However, once the German supplies were cut off and the war showed the immense value of chemicals in the successful prosecution of hostilities, the French Government and private enterprise began to turn their attention seriously to the development of the industry in France.

The manufacture of powder, which is an important branch of the industry, is in the hands of the government, it being, with tobacco, matches, etc., a government monopoly. It will only be necessary to cite a few figures on this one product to show what pre-eminence the chemical industry attained in the eyes of the French General Staff. The plan of French mobilization in 1914 included the following estimates:

Quantity of powder to be produced during the war, 24 tons a day.

Quantity of other explosives to be produced during the war, none.

No one then supposed that the quantity of explosives on hand would not be sufficient for any war purposes. However, after the first battle of the Marne, the pressing need of chemicals for powder and explosives began to develop. It was necessary to create factories almost over night to meet the ever-growing demands of the army. The original provisions, cited above, were doubled many times over, so that by June 25, 1917, the estimates of army needs were the following:

Quantity of powder to be produced, 640 tons a day.

Quantity of other explosives to be produced, 1,100 tons a day.

All this productive capacity, no longer needed for war purposes, can be utilized to build up the chemical industry to a position where France will be independent of foreign sources of supply.

Clay Storage Within the Factory

The December issue of the *Journal of the American Ceramic Society* contains an original article by T. W. Garve, embodying the essentials of adequate storage space and material-handling equipment within the factory, with numerous sketches to illustrate definite layouts.

"To insure continuity of operation it is necessary to have a supply of crushed and ground shale or clay on hand to bridge over breaks and delays and to keep the machinery running ahead of the bin. It is well for the superintendent, and for the men, to know in the morning that there is enough clay supply on hand within the factory to see the day through for production. Besides, any further handling and storing of clays will improve the quality of the clay by intermixing of the particles and their exposure to air.

"Bins employed for such purposes are usually built overhead. This will put the storage out of the way and allow for passage below and for the installation of feeders at the bottom for continuous and automatic feed to the grinding or pugging machinery.

"For delivering raw shale or dry lumpy clay to the factory it is well to dump the contents of the car into a pocket at the bottom of which a plate feeder is operating to insure a steady uniform charge of material to the crusher (or dry pan).

"If a crusher is used ahead of the dry pan, it is proper to place a storage bin between them for keeping crushed material on hand. The crushed material can be fed out of such a bin by means of a reciprocating plate feeder as before or by a disk feeder. The ground material should be stored again above the pug mill with a disk feeder to permit of fine adjustments."

The principles covered in this paper involving storage capacity for raw material and product of machines may well be applied to chemical plants where considerable material is involved in the daily operations.

Nickel Brasses

A Summary of the Work of Leon Guillet Published in "Revue de Metallurgie"
of 1913 and 1920 on the Important Role Played by Nickel in the
Manufacture of Low-Copper Ternary Brasses

AS A RESULT of a systematic study of special brasses¹ it appeared that only nickel, iron and manganese, of several other elements, raised the "fictitious composition" of the ternary alloy. That is to say, whereas most of the alloying elements acted as though they replaced zinc, these three seemed to replace copper. Nickel was much the most powerful in this action, and it appeared desirable to investigate these alloys in detail² in the hope that desirable commercial alloys might be discovered. Theoretical considerations expounded in the former articles¹ led to the expectancy of alloys which could be hot-worked, even though very low in copper, and cold-worked, though relatively low in copper. With approximately normal copper, a little nickel would doubtless increase the elongation, and therefore the ease in cold-working, drawing or stamping. It can readily be seen that if a cheap addition metal could be discovered whose coefficient of equivalence were sufficiently small, a very much cheaper alloy might probably displace the ordinary brasses.

COEFFICIENT OF EQUIVALENCE

Four series of alloys were studied, of 50 and 55 per cent copper, sand- and chill-cast respectively. In each it was desired to replace successively 0.5, 1.0, 2.0, 5.0 and 10.0 per cent of the zinc by nickel. Virgin metal of highest purity was used, so that the resulting bars analyzed only traces of tin and lead. Actual contents of copper, nickel and iron are tabulated.

To determine the coefficient of equivalence the 55 per cent copper brasses of Series I (Table I) were selected. Since t had previously been determined¹ to be less than 1, if one started at the upper limit of β a little nickel would give microscopic field of $\alpha + \beta$. Experimentation quickly indicated that annealing the castings at 750 deg. C. for two hours was necessary in order to normalize the structure and permit accurate microscopic analysis.

As seen in the table, t , the coefficient of equivalence, lies between -1.1 and -1.4, -1.2 being the average. Series II, of practically the same analyses, cast in sand, gives limits and average (-1.4) slightly higher. On the whole, -1.3 seemed to be the most probable value. Series III and IV were available to check this figure, which, within the available limits, was quite close. See especially alloys Nos. 16 and 22. Nos. 17 and 23 are good, considering the high amounts of nickel present.

Alloy 21 (Cu 49.52, Ni 2.28) gives a single microscopic constituent, whether a raw casting or annealed. It is notable, however, that it develops a coarsely polyhedral grain on reheating following no working of any kind, a phenomenon long regarded by many metallurgists as extremely rare if not impossible. Fig. 1,

alloy 23 after annealing, shows the β constituent clearly in a fine eutectoid, a structure never found in ordinary brasses.

MECHANICAL TESTS

All the melts described were subjected to the ordinary static tension and Brinell test. Impact results on notched specimens are also tabulated in Tables I to IV inclusive. Hardness was determined on unannealed castings. The figure for elastic limit is doubtful in almost all cases on account of the well-known difficulty in determining the limit of proportionality in brass specimens. Contraction is also difficult to measure on account of irregularities in the necked area.

EFFECT OF NICKEL ON 50 AND 55 COPPER BRASSES

Inspection of the tables shows that nickel betters the mechanical properties of these brasses if the fictitious composition is sufficiently high. Especially in the 50 per cent copper brasses, Alloys Nos. 15 and 21 (2 per cent nickel) show a very great increase over similar melts containing half as much. Five per cent nickel gives an even greater advantage, while the 10 per cent nickel alloys are quite remarkable.

Comparison of alloys 16 and 22 with Nos. 6 and 7 shows that in general the properties of the ternary alloys correspond fairly well with those of a real alloy having a composition approximating the fictitious composition of the former. However, the important specific effect of nickel can be seen most notably in increasing the strength. Alloys of the same fictitious composition, yet containing widely varying amounts of nickel, will for the same reason also show variations in properties; compare alloys 2 and 22. For this reason, predictions based upon microscopic study and fictitious compositions

¹Revue de Metallurgie, Memoirs, 1905, p. 97, and 1906, p. 242. Summarized in CHEMICAL & METALLURGICAL ENGINEERING, VOL. 24, No. 4, p. 177, Jan. 26, 1921.

²Revue de Metallurgie, Memoirs, 1913, vol. 10, p. 1130.

FIG. 2. EQUILIBRIUM DIAGRAM FOR COPPER-ZINC ALLOYS
After Gulliver, "Metallic Alloys," p. 267

must be made with circumspection and a good knowledge of the effect which the third element will exert by its own right.

Yet it could be expected that since nickel increases the elongation of brasses relatively low in copper, a brass with a little nickel could be worked or drawn better in the cold, an expectation abundantly verified in practice. Again, if nickel be added to a binary brass which can be worked hot and whose constitution is $\alpha + \beta$, but nearly all α (say a 62:38 brass), all the β is suppressed and it may be rolled hot only with difficulty. This change may be much intensified in commercial production, owing to the temptation of remelting nickel-plated ware whose base might be anything, thus

introducing many unknown impurities into the mixture. Inspection of the table shows that remarkable strength, ductility and toughness are had in 49:41:10 alloys³ but more especially in 54:41:5 (alloy No. 10). Rolled and annealed metals of composition 55:43:2 and 50:45:5 were found to have ultimate strengths of from 64,000 to 71,000 lb. per sq.in., an elongation of from 33 to 45 per cent, resiliency of 10 kg.-m. on grooved 10 x 10-mm. test-piece, and Brinell hardness of 100. The war stopped researches along these lines, and the first commercial production of 55:43:2 appears to have been undertaken in the United States. However, even before the war the following results were obtained in French practice:

Type A		Type B

34.....	36.26	21.82	72.4	62
35.....	35.86	23.49	77.4	α
36.....	30.57	22.70	63.8	56.5
37.....	25.01	24.81	58.1	β
38.....	25.74	27.76	70.8	56.5

When next approaching the study of these brasses,⁵ it appeared desirable to discover whether the properties of a 50:45:5 brass (strength, toughness, incorrodability and pleasing color) could be had by decreasing the copper and increasing the nickel.

A series of test-pieces of the compositions given in Table V were prepared, attempting to add nickel in such proportions as to maintain the fictitious compositions between about 55 and 58 per cent.

Fictitious compositions of the alloys formed of $\alpha + \beta$ constituents were determined microscopically to within 0.5 per cent and results tabulated. It is evident that there are important differences between the fictitious compositions when determined microscopically and calculated. Calculating back with the formula

$$t = 1 + \frac{100}{q} \left(\frac{A - A'}{A'} \right)$$

it is found to vary between -0.9 and -1.2 , the smaller when the copper content is lower.

It may be noted that the color of the alloys is as follows:

Alloy No.	Color
24.....	Pale gold
25.....	Pale gold
26.....	Yellowish white
27.....	White and yellow, changeable
28.....	White and yellow, changeable
29.....	Silver white

ROLLING TESTS

To discover the possibility of forging and rolling, tests were made on all brasses under the same conditions—namely, temperatures of 650 to 750 deg. C., same rolling mill and passes at same velocity and pressure, starting with 80-mm. diameter ingots and ending with 20-mm. round bars.

The results obtained in rolling tests are noted in Table VI.

TABLE VI. ROLLING TESTS ON HIGH-NICKEL BRASSES

Alloy No.	Results
24.....	Easy to roll and without defects
25.....	Easy to roll and without defects
26.....	Very difficult to roll. Cracked
27.....	Easy to roll without defects
28.....	Difficult to roll without defects
29.....	Difficult to roll without defects
30.....	Easy to roll without defects
31.....	Small cracks when rolled
32.....	Cracks badly from start
33.....	Breaks in pieces from the start

Alloys 27 and 30 appeared worthy of thermal investigation, since they have unique ductility when hot. There should be an intimate relation between the correct

temperature for forging, the transformation temperatures and variations in mechanical properties. Their microstructure is given in Figs. 3 and 4.

The alloys tested and the results obtained are given in Table VII. Fusion points have been determined with the Coste apparatus; transformation points with the Saladin-Le Chatelier double galvanometer.

While the transformation points in the ternary brass approximate those of binary alloys with the former's

..	40	60	...	...	840	840	470	450

fictitious composition, it is evident that these temperatures are raised by nickel, but the elevation is not directly proportional to the nickel content.

EFFECT OF ADDED METAL

In a general way when a third element is added to a copper-zinc alloy the following may take place:

(a) A special constituent may be formed, consisting of the isolated added element, or of a combination of this element with copper or zinc, or of a new solid solution. For instance, lead appears as a special constituent (rounded globules) when present to the extent of 1 per cent or more.

(b) The eutectoid point may be displaced to the right or to the left, creating a fictitious composition when determined microscopically, which may be respectively above or below the copper content of the actual chemical analysis. It has already been shown that aluminum, tin, silicon and magnesium, having a coefficient of equivalence for zinc greater than 1, move the β eutectoid (point b_2 in Fig. 2) to the left and at the same time the brass assumes a fictitious composition in copper less than the real. On the other hand, iron, manganese and nickel, having $t < 1$, move b_2 to the right, and the fictitious copper content is higher than shown by chemical analysis.

(c) The eutectoid point may be displaced not only horizontally but vertically—i.e., the eutectoid horizontal may be lowered or raised. In this case extremely important variations from the normal constitution of the fictitious binary alloy may result. In a general way, if the point is sufficiently lowered (probably to about 350 deg. C.) the structure after slow cooling becomes martensitic. Such a phenomenon is indicated by Robin's work on bronzes, and by the structure of many special steels. If the transformation point was lowered to below ordinary temperature, the structure would be polyhedral (austenitic in steels). If, on the contrary, we consider a non-resolved eutectoid—as is the case for brasses—and the added element raises the eutectoid temperature, the two constituents of the eutectoid will have opportunity by time and high-temperature mobility to coalesce and appear, especially when the rise in temperature is sufficiently important.

Data on thermal analysis given in Table VII show one important rise in the location of the eutectoid temperature; whereas for normal brasses this transforma-

⁵Revue de Métallurgie, July, 1920, p. 484.

FIGS. 3 AND 4. BRASSES NOS. 27 AND 30 RESPECTIVELY, SHOWING GREAT DUCTILITY

tion on cooling takes place at 450 deg. C., when 10.35 per cent nickel it occurs at 660 deg. C.

In a slowly cooled sample of alloy 27 or 28 one would therefore expect to see both the α and γ constituents under moderate magnification, an expectation confirmed by Fig. 5.

This has already been noted by Carpenter. Further studies to be described later show that the resolved eutectoid appears under circumstances which can be predicted if the rise of the transformation point is known. This is a very remarkable fact from the point of view of the general theory of hardening.

MECHANICAL PROPERTIES AT ORDINARY TEMPERATURE

Tests were made on cast and rolled metals as shown in Table VIII, determining the ultimate strength, elastic limit, per cent elongation after breaking, contraction

(which is defined by the relation $\frac{S - s}{S} \times 100$), impact strength of notched 10 x 10-mm. bar, and hardness. For tension tests the pieces were 13.8 mm. diameter (0.54 in.) and 100 mm. (3.94 in.) between punch marks.

The alloy which has the most remarkable mechanical properties is the No. 27 (Fig. 3), analyzing 46.3 per cent Cu and 10.3 per cent Ni, but it possesses a yellowish glint, and this might be a hindrance for some uses.

Alloy No. 30, 40.4 per cent Cu and 14.4 per cent Ni

(Fig. 4), is of an exceptionally white color and has very interesting mechanical properties.⁶

From the study of the data it can be seen: First, that if we consider the relations between fictitious compositions and mechanical properties, the most interesting alloys are those whose fictitious compositions lie between 57 and 60 per cent. It is well to remember that this is also the case for the binary brasses which give relatively high value in this range (ultimate 46,000 to 54,000 lb. per sq.in., and elongation 35 to 40 per cent).

Second, there are a number of alloys which present the microscopic aspect of ordinary brasses ($\alpha + \beta$) and which do not have any interesting properties. This is a new fact which has not been brought out in previous tests on special brasses, due perhaps to the fact that the work was not done on sufficiently various compositions. An instance is Fig. 6 of alloy 36.

There is no question that when nickel is sufficiently high it alters the properties of the solid solutions considerably, or at least of the β solution, which becomes extremely fragile (alloy No. 37; see also Table V).

INFLUENCE OF COLD-DRAWING

It is evident that the brasses which can be rolled could also be cold-drawn if they possess sufficiently high elongations. But it is to be noted that the greater part of these alloys having a high ultimate strength also possess a high elastic limit—at least higher than those of ordinary brasses—and, due to this fact, the speed of drawing has to be small.

In general, it is not easy to determine the elastic limit.

Table VIII also shows the influence of drawing on the mechanical properties of three of the alloys. The figures have been obtained after one draw on a 20-mm. (0.79-in.) round bar, reducing it 2 mm. (0.08 in.) in diameter.

INFLUENCE OF LEAD

It is known that lead greatly facilitates working ordinary brasses and that all the alloys for machine-finishing contain from 1 to 3 per cent lead. As noted

⁶The alloys containing less than 50 per cent of copper have been patented by the Société Métallurgique de la Bonneville.

					Rolled and annealed	64,900	30,300	26	24.7	5.9	158	112

above, this element retains its individuality in the alloy, forming an inclusion which renders the turnings more fragile and less harmful to the edge of the tool. However, this isolated lead lowers other mechanical qualities of the alloy.

Alloys starting with 45 Cu, 45 Zn, 10 Ni were tested, with which 1, 2, 3 and 4 per cent of Pb were substituted for zinc. Microscopical examination showed the presence of globules in quantities increasing with the lead content.

From the inspection of Table IX one might think that some results have been confused, but this is not the case, and the tabulated figures have been verified with the greatest care. It can be seen that lead up

is low, especially alloy No. 30 (40 Cu, 14 Ni), the addition of lead lowers these properties even more and the products obtained clearly show fissures even after the first pass. Thus the alloy 41.52 Cu, 14.48 Ni, 2.25 Pb, 14.48 Zn could not be rolled.

MACHINING QUALITIES

Appreciation of the machining qualities of a metal varies from shop to shop and even from machinist to machinist.

A series of opinions on alloys of the three types 50:44:6, 45:45:10 and 40:46:14 collected from different plants proved that these alloys can easily be machined in all cases, although not as easily as ordinary brasses. The presence of lead undoubtedly facilitates the machining; the chips in this case are short and easily separated from the tool.

VARIATION OF THE PROPERTIES WITH VARIATIONS IN TEMPERATURE

Some alloys were studied at high temperatures which had been found to be quite difficult if not impossible to roll.

It resulted that the hardness diminishes rapidly as the temperature increases, reaching a value of about 50 at 500 deg. No reliable results could be obtained for temperatures above 700 deg. C.

Variations in resiliency are much more interesting and the harmful influence of lead is very marked. In alloys without lead the resiliency is increased remarkably at about 700 to 800 deg. C. (from about 2 kg.-m. to about 9), and it can be surmised that such alloys might be rolled if it were done at between 700 and 850 deg. C.—i.e., at a temperature higher than that used for brass. This fact has also to be taken into consideration when stamping nickel brasses. High-lead samples showed little change in impact-strength with temperature.

CONCLUSIONS

The results indicate the great value of nickel in the manufacture of low-copper brasses. From the industrial point of view, this study describes some alloys of exceptional qualities possessing ultimate strength up to 90,000 lb. per sq.in. with 20 per cent elongation and a resiliency of 8 to 10 kg.-m., very interesting variations in color from white to gold yellow, and a high resistance to atmospheric corrosion.

It can be expected that nickel is destined to play the same important rôle in the manufacture of copper alloys as it does in that of steels.

It is to be noted, however, that brasses with very high nickel contents can exhibit good microstructure ($\alpha + \beta$), yet not have any valuable special property.

FIG. 6. BRASS NO. 36 (Cu 30.6, Ni 22.7). $\times 200$

to 3 per cent is in reality quite harmless to the mechanical properties of the alloys. Compare especially alloys Nos. 44, 45, 46 and 47 with alloy No. 27.

DIVERGENCE BETWEEN THE PROPERTIES OF AN ALLOY WHEN ROLLED AND WHEN CAST

Special attention is called to the pronounced divergences between the properties of the alloy when rolled and when cast. This is due to the fact that the reheating followed by mechanical work renders the microstructure of the metal more homogeneous.

No particular difficulty has been noted in the rolling of these alloys; it was as easy as the same operation on products not containing lead. But when the original alloys are rolled with difficulty, or when the elongation

Ownership of Highways and Streets

BY CHESLA C. SHERLOCK

RECENT press dispatches contain a very interesting account of a dispute between the Nichols Copper Co. and the Borough of Queens in New York City over the ownership of a street running through the factory grounds. The press account states:

"The disputed street is about ten blocks long and extends from Creek St. to the Newtown Creek waterfront. The Nichols company owns the land on either side and its property is partly improved and partly a place for the storage of coal. Down the middle of the street runs the narrow-gage plant railway and it is fringed with heaps of old iron, lumber and other materials. Residents of the Newtown section, complaining that access to the waterfront was denied them, besought Borough President Connolly to do something."

As soon as Mr. Connolly was advised that the company was putting up iron gates across the street to shut out the public, he gathered a force of 100 borough laborers and proceeded to tear up the railway and to clear the street of debris, claiming that it belonged to the city. There was no clash, the company contenting itself with court action and giving notice that the borough would be held responsible at law for all damage done to what it claims to be its private property.

There is probably no subject which has called for as much attention from the courts as that of the ownership of streets and highways.

TEST OF OWNERSHIP OF A WAY

The test of the ownership of a way, according to Ruling Case Law and backed up by numerous decisions of the courts, "is whether it is an open public way or one for the exclusive benefit of an individual or certain individuals. It is the right of travel by all the world, and not the exercise of the right, which constitutes a way a public highway, and the actual amount of travel upon it is not material. If it is open to all who desire to use it, it is a public highway, though it may accommodate only a limited portion of the public or even a single family, or though it accommodates some individuals more than others. Giving a private way a name, however, does not make it a public highway or thoroughfare."

This expression may be said to lay down the general principles governing in general cases. Seeking to apply it to the facts in any particular case, however, it is necessary for us to delve still deeper into the law.

Highways generally are established in two ways: First, by affirmative act under a statute giving that right; second, by long-continued usage as such. The latter principle applies in most jurisdictions; in some it is expressly abrogated by law.

It is quite apparent that the street in controversy had been used as a public way by some of the Newtown residents and that the company gradually assumed control of it for private purposes, at last attempting to shut out the public entirely.

HOW STREETS MAY BE DISCONTINUED

Streets may be discontinued at law only by abandonment. This does not mean by simply ceasing to use them, but it means by the affirmative act of publicly abandoning them.

There is a maxim in highway law which reads, "Once a street, always a street," and it holds good unless the

street is legally discontinued by the method prescribed in the statute relating to such matters.

In a New York case, it was held that a street was not discontinued or destroyed where an abutting property owner constructed a wharf upon said street.

In a Rhode Island case, which seems to be squarely in point with the borough case mentioned above, it was shown that a riparian owner had platted his land into streets, lots, squares, one of such streets being below high-water mark; the street was subsequently filled out, and the adjoining lots were sold to another party, who sought to use the street for private purposes just as the Nichols company attempted to use the street mentioned above, and not only that, but this owner attempted to close the street to the public. The court held that "the fact that the title to the several lots over which the highway runs becomes vested in the same owner does not extinguish the way, or justify such owner in closing it up, where it is appurtenant to other lots, as when it leads from other lots to tidewater."

In this Rhode Island case it was held that one lot owner had the right to keep that street open in the name of the public, because the closing of it cut him off from the waterfront.

Private individuals or private companies have no right to obstruct public ways, to lay tracks upon them or to close them up, except by express grant from the public. In case of the discontinuance of a public way, it cannot be assumed or inferred from the fact that it is seldom used by others than those owning property on both sides of the street; it can be a fact only by the affirmative act of the public in the method set out by law.

United States Has Over One-Quarter Million Producing Oil Wells

According to the figures compiled by the United States Geological Survey there were 258,600 oil wells in the United States with an average daily production of 4.98 bbl.

Pennsylvania ranked first in number of wells (67,600), but lowest in average daily production (0.3 bbl.); Oklahoma followed next with 50,700 wells with an average daily production of 6 bbl. Texas, Louisiana, California and Wyoming and Montana, although possessing fewer wells, had a greater daily average production, of 27, 31.8, 32.3 and 55 bbl. respectively.

The following table gives the district, number of wells and the average daily and actual output in the United States:

	No. Producing Wells	Daily Average Output, Barrels	Nov. Actual Output, Barrels
Texas central and north ...	9,400	22.9	6,714,000
Gulf Coast	1,700	49.7	2,775,000
Total, Texas	11,100	27.0	9,489,000
California	9,490	32.3	9,340,000
Oklahoma	50,700	6.0	9,031,000
Kansas	15,700	7.4	3,578,000
Louisiana	2,700	31.8	2,615,000
Wyoming and Montana ...	1,000	55.0	1,432,000
Illinois	16,800	1.7	846,000
Kentucky	7,800	3.2	734,000
West Virginia	19,500	1.1	656,000
Pennsylvania	67,600	0.3	603,000
Ohio	39,600	0.5	602,000
Indiana	2,400	1.1	81,000
New York	14,040	0.2	75,000
Total	258,600	4.98	39,090,000

Drying Storage Battery Plates

Low production cannot always be attributed to the inefficiency of labor, as seems to be the tendency these days. Very often it is due to antiquated equipment and obsolete methods of manufacture, which become the limiting factors in production, and no matter what speed is obtained up to this point the output of a plant is limited to the slowest operation in the process of manufacture.

Ninety per cent of all materials made must be dried at some stage of their manufacture, and generally speaking the drying operations require considerable time, varying from the fifteen minutes required for drying

MACHINE FOR DRYING STORAGE BATTERY PLATES

cotton and wool stock to from one to two weeks for high-tension porcelain insulators.

In the manufacture of storage batteries, the positive plates are formed by pasting a mixture of ammoniacal red lead into specially molded metallic lead grids, and the negative plates by pasting a mixture of lead peroxide into grids of the same type, the plate then being dipped into dilute sulphuric acid. Both positive and negative plates must then be thoroughly dried, since after the drying operation the plates are charged with electricity by the usual method and if there is even a small amount of moisture remaining in the plate the charging will cause the active material to crumble away from the grid and the plate must be discarded.

After the pasting process, the plates are inserted in racks preparatory to drying. Under the old system of drying the racks containing the plates were put into closets to dry. These closets were huge affairs of wood construction occupying a great amount of floor space and heated by means of steam coils which also formed the shelves for holding the racks containing the plates. As each rack was filled with wet plates, it had to be carried from the pasting table to the shelves on the closet. Here it required from twenty-four to forty-eight hours for the plates to dry, depending on the humidity of the surrounding atmosphere and with no certainty of uniform results or definite length of time to dry.

The length of time required to dry the plates by the old method and the lack of uniformity of results presented a serious obstacle to one of the largest storage battery manufacturers in this country when large-scale production was desired. The difficulty was practically

overcome by the use of a Hurricane drier of the tunnel truck type, manufactured by the Philadelphia Drying Machinery Co., Philadelphia, Pa.

This machine is constructed of angle-iron framework to which panels are clamped, consisting of two sheets of steel, beveled and fastened together on the edges, thus forming an air-cell and providing insulation for the drier. The machine is divided into two compartments, one holding the steam coils which provide the heat for the drying, the other holding the trucks of plates being dried. The drying is accomplished by the circulation of large volumes of hot air by fans located in the partition between the two compartments.

After the plates are pasted and inserted into the racks, they are loaded on to a waiting truck and when fully loaded the truck is run into the drier. Here the plates are dried in a few hours, the time required depending on the area and thickness of the battery plate.

The drier is built to hold six specially constructed trucks in the drying chamber at one time, and as a truckload of wet plates is pushed into the machine at the feed end, a truckload of dry plates is removed from the delivery end, thus reducing labor and floor space to a minimum with the assurance that the material will be dried in a definite time.

Multiwhirl Subcooling Condenser

The construction of the multiwhirl subcooling condenser designed for use in oil refineries, particularly for the condensing and subcooling of gasoline, kerosene or any other vapors is shown by the accompanying cut.

The vapors to be condensed enter the tubes at the top and are condensed and cooled in their passage through the tubes. The resulting distillate is taken off at the bottom, the tubes being arranged single pass. The condensing and cooling water enters the shell at the bottom and travels upward through the helical path and leaves the condenser at the top, this arrangement insuring contraflow operation.

The unusual feature of this condenser, built by the Griscom-Russell Co. of New York, is the patented helical baffle, which insures a maximum length of water path for a given length of shell and a minimum water pressure loss. The helical baffle directs the water in its flow through the shell without appreciably retarding its progress.

The multiwhirl design permits a given size condenser in a much smaller space than has hitherto been possible because the efficiency secured by the use of the helical baffle permits the use of a much smaller amount of condensing and cooling surface than is ordinarily required. The efficient operation of the cooler permits delivery of the given cooling and condensing duty, using about one-third to one-quarter the condensing water required with other types of apparatus, with corresponding reduction in pumping costs. The high efficiency of

SECTION PHOTOGRAPH OF CONDENSER

heat transfer results in a temperature of distillate within a few degrees of the condensing water supply. The helical baffle has been used for the past four years and is, therefore, a tried-out design which has been fully proved in other fields. The entire tube bundle may be removed from the shell, provided such removal is necessary for inspection and cleaning. The tubes are expanded into the tube plates without the use of sweated joints. The upper tube plate is rigidly attached to the shell, but the lower tube sheet floats and is free to move, thus preventing any expansion strains on tube joints. The floating head is outside packed and this construction prevents any possible leakage of water into the oil through faulty packing.

The condenser is made standard with shell of close grain cast iron, water head of cast iron or cast steel, and floating head of cast steel with floating head cover of either cast iron or steel. The tubes are of $\frac{5}{8}$ -in. O. D. No. 16 B.W.G. seamless drawn steel expanded into tube sheets of rolled steel. The helical baffle is of brass. These materials of construction are varied to suit the requirements of the particular installations.

These condensers are built for both low or high pressure operations. They are especially well adapted to various cracking and topping systems. In making estimates on equipment installation, the following data should be had:

1. Pounds of vapor to be condensed per hour.
2. Gravity of liquid—degrees Baumé.
3. Latent heat of liquid.
4. Viscosity of liquid in Saybolt seconds.
5. Boiling point of liquid at working pressure.
6. Working pressure of vapor.
7. Inlet temperature of vapor.
8. Desired outlet temperature of condensate.
9. Per cent of non-condensable gases in vapor.
10. Can non-condensable gas be vented to atmosphere and if not what provision is made to take care of same?
11. Is steam present in vapor; if so how much?
12. Quantity of condensing water available per hour.
13. Temperature of water.
14. Water pressures—pounds per square inch.
15. Fresh or salt water?
16. If fresh, is it hard or soft?

Long Cast Sections Made by Welding Smaller Units

Ingots stripper plungers are extremely difficult to cast, owing to the fact that the cylinders, while 18 in. in diameter and 25 ft. or more long, have walls only 1 in. thick. Inasmuch as it is almost impossible to obtain a perfect core and then anchor it so as to prevent floating, the thickness of the steel is often reduced on certain sides, thereby weakening it and resulting in frequent breakages.

It has been found, however, that these castings can be made much more easily and of more uniform thickness by casting each cylinder in three separate parts about 10 ft. in length each, instead of in one piece, and then welding the parts together by means of thermit welding. All three welds can be machined off at the same time, and as the outside of the cylinder must be machined anyway, practically no more machining is required than if the plunger were cast in one piece. Plungers have been successfully welded in this manner for the past ten years and the welds have stood up perfectly in service.

FRONT VIEW OF THERMIT WELDED INGOT STRIPPER PLUNGER AFTER HAVING BEEN CAST IN SMALLER SECTIONS

In the same way locomotive frames of unusual length for small foundries and other long sections which are difficult to cast in one piece can be cast in shorter lengths and these sections welded together. Welding may also be similarly used for building up shafts and other large sections in inaccessible places distant from transportation or underground in cramped quarters.

Flow-Regulating Valve for Viscous Liquids

The valve sectioned in the accompanying illustration was devised by A. V. Rigby, of the Carnegie Steel Co., and has given general satisfaction on open-hearth and reheating furnaces burning byproduct tar. A regulating orifice in the shape of a wedge 1 in. long and $\frac{1}{8}$ in. wide at its base is cut in the valve seat 1.

A slide valve 2, actuated by hand wheel 3 and limited by an adjustable set screw 4 closely regulates the effective area of the opening through which the liquid must pass from inlet 5 to exit 6. In case the opening should be clogged, the slide 2 is brought forward, pushing the obstruction into the trap 7, while material sheared off by the under surface of the slide is washed out by the flow of liquid when the valve is reopened. Bailey-Lewis, Inc., of Pittsburgh, has the selling rights for this regulator.

Synopsis of Recent Chemical & Metallurgical Literature

Forge Press Operations.—A paper, very important to engineers responsible for forging operations, was presented by EUGÈNE SCHNEIDER before the autumn (1920) meeting of the British Iron and Steel Institute, entitled "An Investigation of Various Forging Operations Carried Out Under Hydraulic Presses." In it the author describes a recording instrument developed at the Creusot works, gives an illustration of the autographic and derived curves for a heavy forging job, and finally a diagram summarizing information on stamping thirty different calibers and designs of shells. By means of such graphs it is possible to predict confidently the proper treatment for strange forgings; hitherto, only a "cut-and-try" process had been the guide.

Fig. 1 shows a photograph of the recorder. A strip of paper is wound around drum A by means of wire B connected to the ram and wound in turn about the drum-end C, made slightly conical to compensate for the thickness of the overlapping paper. A pipe, as large and short as possible, connects the press cylinder to manometer D; pressure moves the pointer, and through the agency of a light sheave and silken cord, drives a tiny counterweighted pen carriage E at right angles to the paper-travel. Such a curve as that shown on the drum

FIG. 1. RECORDING INSTRUMENT FOR FORGING PRESSES

evidently records the position of the ram and the pressure in the cylinder at any instant. Times corresponding to these movements are recorded in a unique manner. A constant-speed-motor F drives an endless chain at right angles to the paper-edge. To this chain is attached pencils G, one of which is always making a mark on the paper. Since the transverse speed of the pencil is uniform, the slope of its trace is a measure of the speed with which the paper (that is, the ram) moves.

In order to record both up and down ram-movements on paper constantly moving in the same direction, wire B is pulled by a second drum, mounted on the same shaft as a fine-toothed ratchet wheel. To right and left of the latter and loose on the same shaft are mounted

TABLE I. SYNOPSIS OF PUNCHING

No.	Type of Forging	Weight in Kg.	Nature of Blank Employed—Diam. in mm.	Lgth. in mm.	Thickness of Bottom in mm.	Depth of Punching in mm.
1	75 mm. shrapnel.....	5.6	Round, 82.....	138	22	116
2	H.E. 75 mm. shell.....	7.8	Round, 82.....	190	30	160
3	Howitzer shell 58 mm.....	4.8	Round, 82.....	117	20	97
4	105 mm. shrapnel.....	13.3	Round, 115.....	165	30	135
5	155 mm. cartridge.....	17	Round, 172.....	95	22	73
6	H.E. howitzer shell, 120 mm.	28	Round, 138.....	240	30	210
7	H.E. howitzer shell, 105 mm.	23	Round, 115.....	285	40	245
8	H.E. howitzer shell, 155 mm.	56.5	Square, 145; diag., 186.	360	35	325

30	H.E.....	1,400	Octagon, diam., 580..	970	130	840

sprockets carrying counterweighted link chains fixed to the ram, but reeved oppositely. Thus when the ram is going down, the right sprocket ratchets the drum forward, and when the ram is being raised, the left sprocket ratchets the drum forward, the right sprocket then idling.

Calibration is effected by attaching a hand pump to H, holding a certain pressure, indicated by the standardized manometer J, and drawing the paper forward slightly. The time is checked by measuring with a stop watch the time necessary for, say, twenty complete circuits of the first pencil G, and computing its speed.

The diagram in Fig. 2 assembles information on forging of thirty different types of shells and tubes listed in Table I. Many different factors affect the work of forging T (defined as the necessary pressure in kg. per sq.mm. of the greatest diameter of the punch). After temperature—which is held constant at 1,050 deg. C.—the greatest influence is exerted by the thickness of the walls e (Fig. 3) and the diameter of the punch. The ratio between the area of the side wall (an annulus with thickness e and inner diameter d) and the area of the punch is noted by Y and is called the coefficient of spread.

$$Y = \frac{4e(d+e)}{d^2} \text{ and } Y \propto \frac{1}{T}$$

If the diameter of the punch d is constant, the work of forging T evidently decreases with increase in wall thickness e. If the wall thickness e is constant, the work of forging decreases with the diameter of the punch. Therefore, Y has been computed for each forging and plotted below the horizontal axis. Three general classes have been distinguished, the dotted lines referring to thin walled forgings ($Y = 0.76 \pm$), the continuous lines to medium-walled forgings ($Y = 0.95 \pm$), and the dot-and-dash line to thick forgings ($Y = 1.2 \pm$). Heavy lines below the axis also connect corresponding punch-diameters. Values of Y and d not falling near the curves such as for forging 24 present in general no anomalies.

The length of the stroke is of influence chiefly on account of the time the metal is pressed and cooled

FIG. 2. DATA ON WORK REQUIRED FOR A PUNCHING OPERATION

Relationship between forging pressure in kilograms per square millimeter, diameter of punch, coefficient of spread and coefficient of travel for various operations, grouped in three classes.

against the die. The coefficient of travel K is defined as the ratio of length of stroke to diameter of punch, and is plotted above the horizontal axis, both for round and square billets, the latter being the higher. Other variables which have been eliminated are the shape and surface condition of punch and die, the speed of the press, the "spread" (or $e \div E$, see Fig. 3), the temperature of the tools, and the lubrication. Finally, the graph contains what is doubtless the most important information, viz., the work of forging, each point T being an integration of all these factors for a particular job, as determined with the aid of the recorder described above.

FIG. 3. SKETCH OF PUNCH AND DIE

(a) What pressure will be required to make a forging with $d = 255$ mm. and $e = 48$ mm.? Y is figured to be 0.89, consequently the work would be between that required for thin and for medium forgings. Running up ordinate 48, the required pressure is found to be about 15 kg. per sq.mm.

(b) Suppose a forging with $d = 255$ mm. is required and only a 650-ton press is available (a press which gives a maximum pressure of 12.8 kg. per sq.mm.). Running across abscissa 12.8 to its intersection with the curve T for thick forgings shows that a wall thickness of at least 60 mm. must be provided, and the die must evidently have a diameter not less than 375 mm. Y figures 1.16, consequently our assumption that the forging would lie in the "heavy" class is justified.

Other instruments may evidently be substituted for the manometer D (Fig. 1) and the working of a pump, machine tool or other machine can be studied. When applied to presses, it has furnished data for proper conversion of steam-driven pumps into electrically-driven pumps, and, as remarked above, for the solution of all forging problems connected with the scientific management of that department, enabling the production to be largely increased.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Electrodes for Electric Arc Welding and Cutting.—In the manufacture of electrodes for the electric arc welding and cutting of metals the electrode covering consists, in addition to calcined magnesite, powdered aluminum and sodium silicate, of calcium carbonate and either graphite, iron peroxide or ferrous silicate, or graphite in conjunction with iron peroxide or ferrous silicate. The electrode is thus rendered suitable for overhead or vertical welding or welding in confined positions where the electrodes have frequently to be bent, and also allows for the variability of the carbon and silicon contents of the metal core. In an example a powder is made consisting of 100 g. of calcined magnesite, 100 g. of calcium carbonate, 33 g. of powdered aluminum, and 33 g. of graphite, which is made into a paste by adding 11 to 12 fluid oz. of a solution of silicate of soda of strength indicated as 40 deg. on Twaddell's scale. The proportion of iron peroxide when used may be 75 parts by weight and of ferrous silicate 66 parts by weight. (Br. Pat. 152,257, H. W. BOORNE, London; Dec. 22, 1920.)

Treating Complex Ores.—Complex ores or their products are roasted with an alkali chloride at about 400 deg. C. or lower with access of air so as selectively to chloridize the lead and silver or at similar or higher temperature so as to chloridize all the metals, and the product is then leached with hot alkali chloride solution to dissolve the lead and some silver, and afterward, if desired, with a solution of sodium thiosulphate to extract the silver. The first leaching solution is treated with metallic zinc, galvanized iron, aluminum or the like to obtain the lead and silver, and the deposited metal may be compressed under water to avoid oxidation, and is finally melted down. The second leaching solution is mixed with a sodium chloride solution and similarly treated to obtain a richer argentiferous lead; or the metals may be obtained from both solutions electrolytically.

The residue from the leaching is treated by the "acid-oil froth process" to obtain a zinc concentrate. (Br. Pat. 152,289; not yet accepted; H. J. E. HAMILTON, North Broken Hill, New South Wales; Dec. 22, 1920.)

Artificial Marble.—Artificial marble is produced by making several separate mixtures of different colors and consistency, superimposing the mixtures in layers, and stirring them together with or without shaking in such a manner as to avoid complete mixing. A dry mixture of 1 part portland cement, $\frac{1}{2}$ part silver sand and $\frac{1}{2}$ part pulverized marble is moistened with water to which is added coloring matter free from sulphuric acid to form a comparatively thick mortar. "Flame markings" are produced by mixing a similar composition of different color with a larger proportion of water, and the composition for veins with less water. These mixtures are superimposed and turned over with a trowel or the like to mingle the colors. The mass is then shaken in molds without compression, and after drying the face layer is ground off. For reinforced concrete, the marble mass is placed in the mold, and while still moist the reinforced concrete is superimposed. (Br. Pat. 152,359; not yet accepted; D. JAGER, Amsterdam, Holland; Dec. 22, 1920.)

Alkali Percarbonates.—Solid alkali percarbonates are obtained by treating sodium carbonate with hydrogen peroxide in presence of sufficiently limited quantities of water to produce the solid product directly, and of sodium chloride for salting out the product. A previous calcination of the sodium carbonate and the addition of anti-catalyzers such as sodium silicate, magnesium chloride and magnesium-sodium silicate are advantageous. (Br. Pat. 152,366; DEUTSCHE GOLD & SILBER-SCHNEIDEAUSTALT, VORM. ROESSLER, Frankfurt on Main; Dec. 22, 1920.)

Phenol-Aldehyde Condensation Products.—The condensation of phenols with formaldehyde or its equivalents is effected in the presence of a very small proportion of nitrocellulose or cellulose acetate; the maximum amount of cellulose ester used is about 0.8 per cent reckoned on the phenol. The use of nitrocellulose renders the product odorless, while cellulose acetate also confers increased toughness. In an example, cresylic acid, formaldehyde, caustic soda, and cellulose acetate (0.00025 per cent) are employed; the liquid product is boiled down, baked at atmospheric pressure, and may be further treated in an autoclave. (Br. Pat. 152,384; A. W. WELLER and W. T. ROBINSON-BINDLEY, both in London; Dec. 22, 1920.)

Chromium and Its Alloys.—A process for obtaining chromium from chromic oxide or a mineral such as chromite, for the production of chrome-iron or chrome-steel alloys, comprises the thermo-reduction of the oxide of chromium with calcium carbide in the presence of an alkaline earth oxide, with or without the presence also in the mixture of one or more other reducing agents such as calcium silicide or aluminum. The alkaline-earth oxide is preferably present in proportion at least equal molecularly to that of the calcium carbide. The reaction may be carried out within molten steel and the mixture may be inclosed in thin sheet-iron cases to be immersed in the molten steel. (Br. Pat. 152,399, W. B. BALLANTINE, London; Dec. 30, 1920.)

Anhydrous Magnesium Chloride for the Manufacture of Magnesium and Magnesium Alloys; Magnesium Chlorate.—Hydrated magnesium chloride is converted into the anhydrous body by partial dehydration in a voluminous current of heated air, preferably dried, until the fusion point is raised above 150 deg. C., followed by treatment with a slow current of hydrochloric acid gas to complete the dehydration. During dehydration, fusion of the mass is to be avoided, and the product obtained is porous if a temperature of 500 deg. C. is not exceeded, and of a partly crystalline texture if the temperature is allowed to rise to incipient fusion, 650 deg. C. After dehydration, the product may be fused. The magnesium chloride is preferably employed in the form of needle crystals such as are obtained by cooling a solution having a strength of 80 deg. Tw. from 50 deg. C. to atmospheric temperature. (Br. Pat. 152,401.) The fused anhydrous magnesium chloride, free or practically so from other substances, is used as electrolyte in both a primary and secondary cell. (Br. Pat. 152,402.) The chlorine obtained as a byproduct is absorbed in magnesium oxide emulsion producing magnesium chloride and chlorate, which are separated by crystallization, and the magnesium chloride is again used in the process. To render the process continuous, an additional supply of chlorine is admitted to the absorber. (Br. Pat. 152,403, E. A. ASHCROFT, London; Dec. 30, 1920.)

Acetic Acid, Methyl Alcohol; Acetone.—In order to recover the acetic acid, methyl alcohol and acetone formed by the destructive distillation of wood in suction gas plants, the wash water from the suction-gas scrubbers is passed

over chalk or barium carbonate until a sufficient concentration of acetate is obtained, and at the same time the methyl alcohol and acetone are withdrawn by means of vacuum. The wash water contained in the tank A is pumped into the vessel B, provided with a heating jacket, where it passes through lumps of calcium or barium carbonate and overflows through the pipe *b'* into the vessel D, which also contains calcium or barium carbonate and is fitted with a cooling-jacket. The methyl alcohol and acetone are drawn off from the heated wash water in the vessel B by means of the pump *b* into the condensing coil C. The liquid issuing from the vessel D is pumped into the tank E, from which it can be run back to the scrubbers of the suction-gas plant. The process is repeated until the content of calcium or

barium acetate is sufficient to justify its recovery by evaporation. (Br. Pat. 152,420, J. C. ROBERTS, Hull, England; Dec. 30, 1920.)

Coloring Wood.—In coloring wood black or gray by means of a solution of iron and a solution of tannin, the wood is dried between the successive impregnations and is finally treated with ammonia or other alkali. Logwood extract may be used instead of, or in addition to, tannin, to modify the color. Impregnation may be effected with the aid of vacuum and pressure, and the process may be carried out in the cold or with the application of heat. (Br. Pat. 152,427, R. E. SLADE, London; Dec. 30, 1920.)

Intermediate Products; Dyes.—4-Nitro-2-naphthol is obtained by diazotizing 2:4-dinitro-1-naphthylamine with nitrosyl sulphate or sodium nitrite in concentrated sulphuric acid, pouring the diazo solution into water to precipitate 4-nitronaphthalene-1-diazo-2-oxide, and heating this diazo-oxide with ethyl alcohol, alone or in the presence of a metallic catalyst such as zinc, copper, aluminum or a zinc-copper couple, or a reducing agent such as hypophosphorous acid.

2:4-Dinitro-1-naphthylamine is prepared either by heating 2:4-dinitro-1-naphthol with alcoholic ammonia at 200 deg. C., or by dinitrating an acyl- α -naphthylamine or arylsulphonyl- α -naphthylamine—e.g., aceto- α -naphthalide or *p*-toluenesulphon- α -naphthalide—and hydrolyzing the product—for example, by heating with sulphuric acid.

Azo dyes are obtained in substance or on the fiber by coupling diazo or tetrazo compounds with 4-nitro-2-naphthol; the following products are specified: A dark red wool dye from diazotized sulphanilic acid; an orange dye from diazotized *p*-nitraniline-*o*-sulphonic acid; a purple cotton dye from tetrazotized 4:4'-diaminostilbene-2:2'-disulphonic acid; a purple cotton dye from diazotized safranin; and azo dyes on the fiber from *p*-nitraniline (bluish-red), 2:4-dinitraniline (red), dianisidine (dark blue), and primuline (reddish-brown). (Br. Pat. 152,437, G. T. MORGAN, Birmingham, and BRITISH DYESTUFFS CORPORATION, London; Dec. 30, 1920.)

Purifying Benzene.—Sulphur compounds are removed from benzene and other light oils by treatment at 30 to 90 deg. C. with sulphuric acid of 60 to 85 per cent strength, as by boiling the oil with acid of 73 to 82 per cent strength, or by passing the oil vapor through acid of 70 per cent strength at 84 deg. C. In an example, 500 gal. motor benzene are agitated with 50 gal. acid of 82 per cent strength for about two hours at 83 deg. C. in a sulphonator fitted with a reflux condenser, and the purified benzene is separated by distillation or gravity. (Br. Pat. 152,470, SOUTH METROPOLITAN GAS CO., E. V. EVANS and H. HOLINGS, London; Dec. 30, 1920.)

Solder for Aluminum and Aluminum Alloys.—A solder for aluminum or its alloys is made from 6 lb. of tin, 2 lb. of zinc, 1½ lb. of aluminum, ¾ lb. of lead and ¼ lb. of an alloy of equal parts of copper and aluminum. The ingredients are melted in a graphite crucible with cryolite and lithium fluoride, and the product is fluxed with manganese chloride and run into bars. In use, the solder is applied to the heated aluminum surface; the coated surface may then be united to another similarly treated surface, or may be soldered by means of ordinary soft solder. (Br. Pat. 152,486, H. J. ANSELL, London; Dec. 30, 1920.)

Tanning.—Material to be treated by any tanning, impregnating or like process is submitted to a preliminary treatment consisting in subjecting it to the action of an electric current in pure water. This is stated to shorten and render more economical the subsequent process and also to have a deliming effect. The preliminary treatment in pure water may be conducted with diaphragms or the hide, etc., may be suspended between two poles and subjected to the electric current. The subsequent treatment may comprise electro-osmotic tanning or mechanical tanning or a combination of these processes. In an example, an oxhide delimed with dilute formic acid is electrically treated in pure water for ten hours, being then electro-osmotically tanned in chestnut wood extract of 2 deg. Bé. and subsequently mechanically tanned with a similar extract of 3 deg. Bé. (Br. Pat. 152,641; not yet accepted; ELEKTRO-OSMOSE AKT. GES., Berlin; Dec. 30, 1920.)

Current Events

in the Chemical and Metallurgical Industries

Nitrogen Corporation Bill Sleeping in Committee

At this writing there is apparently little chance for the bill providing for the formation of the U. S. Fixed Nitrogen Corporation. After passing the Senate the bill was referred to the Committee on Military Affairs of the House. Hearings were announced to begin on Feb. 3, but subsequently it was stated that the witnesses, each of whom favored the passage of the bill, had withdrawn their requests to be heard.

There is general feeling that the friends of the bill still have a card or two to play. The effort probably will be made to attach the bill to an appropriation measure as a rider.

Significance is attached to the fact that the Senate Committee on Appropriations has added to the sundry civil bill the \$10,000,000 appropriation for the continuance of work on the dam at Muscle Shoals. The Committee on Appropriations of the House refused to embody this item in the bill it formulated. An effort to put the item in on the floor of the House was unsuccessful.

Chemical Warfare Service Appropriation

Instead of the \$8,000,000 requested by General A. A. Fries for the Chemical Warfare Service during the next fiscal year, the Committee on Appropriations has embodied \$1,500,000 in the Army appropriation bill, which was reported to the House Jan. 29. While the estimates of all War Department activities were reduced one-half on the average, there is a very decided feeling on the part of many members of Congress that the importance of chemical warfare is entitled to more than the committee has reported, which is less than one-half of 1 per cent of the funds made available in the Army appropriation bill.

General Fries states that the appropriation is entirely inadequate and that under it the Chemical Warfare Service not only will lose much ground but will be handicapped in its efforts to keep abreast with other nations in the study of war gases.

In explaining to the Committee on Appropriations the need for a larger appropriation, General Fries pointed out that he needed no less than \$1,754,000 for his investigatory work alone. He revealed that fifty-two separate lines of investigation have been approved by the War Department. Some of these are subdivided so that one item has as many as a dozen subdivisions. Seventy per cent of the amount appropriated, General Fries stated, goes for the salaries of technical employees and the wages of common laborers. To cut the appropriation, General Fries told the committee, means that the work will require twice or three times as long as would be the case were the desired appropriation allowed.

"We worked this over with extreme care," said General Fries, "to get it down as low as possible. We do not want to build up a big force, but we do feel that we are charged with the defense of the entire Army against all chemical warfare materials. These materials affect every man in the Army from the commanding general down to the last private.

"We are operating eleven plants at Edgewood. These expenses at this time are at the rate of \$1,000,000 per annum. In addition, we have the proving ground at Lakehurst, N. J., and we are operating sixteen salt wells at Midland, Mich., from which we get bromine. The Chemical Warfare Service sank these wells and built the plant to connect them up during the war. The brine is turned over to the Dow Chemical Co. to manufacture bromine salts. The manufacture of the salts into the bromine itself is done by us at Edgewood. The company has a contract to furnish 1,000,000 lb. of these salts. The net cost is 30c.

a lb. Delivery will be completed before the end of the current fiscal year."

General Fries told the committee that at the present time the service consists of fifty-nine officers and 900 men out of a total authorized allowance of 100 officers and 1,200 enlisted men. The quota of officers has not been filled, because commissions in the service are unattractive to men possessed of the proper qualifications.

In regard to the chemists employed by the service, General Fries submitted a list of his civilian chemists as follows: One at \$6,000, one at \$4,500, three at \$3,600, one at \$2,100, one at \$2,000, one at \$1,800, one junior chemist at \$2,400, three junior chemists at \$2,000, twenty junior chemists at \$1,800, one junior chemist at \$1,760, one junior chemist at \$1,740, one junior chemist at \$1,700, four junior chemists at \$1,620, two junior chemists at \$1,500, five associate chemists at \$3,000, two associate chemists at \$2,800, one associate chemist at \$2,700, three associate chemists at \$2,600, five associate chemists at \$2,500, one associate chemist at \$2,475, thirteen associate chemists at \$2,400, one associate chemist at \$2,300, one associate chemist at \$2,290, one associate chemist at \$2,220, two associate chemists at \$2,160, seven associate chemists at \$2,100.

Oil From Pennsylvania Shales

Experiments to determine the amount of oil obtainable from Pennsylvania coals and black shales were begun in 1918 by Charles R. Fettke. A preliminary report on this work has been issued recently in mimeographed form by the Pennsylvania Geological Survey. Yields of oil, ammonia and gas (all based on a ton of 2,000 lb.) are given in tabulated form for eighty-four samples. There are also given for comparison results of tests made in the same way on cannel coals of other states and on rich Western oil shales.

The data show that Pennsylvania is not well supplied with rich oil-producing coals or shales. The conditions that produced the valuable anthracite in the eastern part of the state and the high-carbon coals in the eastern part of the bituminous fields drove the oil and gas out of the black shales of those regions, so that good results were obtained only from the coals and black shales in the extreme western and northwestern counties of the state.

Connecticut Valley Section, A.C.S., February Meeting

An interesting program is promised for the next meeting of the Connecticut Valley Section of the A.C.S., which is to be held at the Hotel Elton, Waterbury, Conn., on Feb. 14. Dr. John S. Shearer, professor of physics at Cornell University, will give an illustrated lecture on "Some Recent Applications of X-Rays in the Study of Metals."

Chemical Warfare Service Resolution to Be Submitted to the A.C.S.

A resolution deploring the limitations being placed upon the appropriations for the Chemical Warfare Service and the lack of sympathy shown for this service within the military establishment of the Government probably will be submitted to the American Chemical Society at an early date.

Refractory Plant of Baker Steel Co. Destroyed by Fire

Practically the entire reduction plant of the Basic Refractories, Inc., a subsidiary of the Baker Steel Co. of Pennsylvania and located in Natural Bridge, N. Y., was destroyed by fire on Jan. 24. The loss was \$100,000.

Hearings Against Shadyside-Edgewater Plants Postponed

On Jan. 29 an adjourned hearing was heard in New York City before Herman Biggs, Commissioner of Health of the State of New York, to hear the complaint of the West End Association and the city against certain chemical manufacturers with plants in the State of New Jersey.

The concerns involved are: The Barrett Co., the General Chemical Co., the Corn Products Refining Co. and Spencer Kellogg & Sons, Inc. As these corporations all do business in New York State, these hearings have been held to give the defendants an opportunity to explain their actions. Chapter 292, Laws of 1917, provides an amendment to the General Corporation Laws of the state, whereby offending corporations may be prevented from doing business within the state, if they continue to commit such nuisances as that in question. Action was begun in 1918 by a group of persons who live in Riverside Drive and the western part of New York City. It was claimed that during periods of a west wind the fumes given off by these four plants rendered the air foul and made life miserable for the residents. The defendant companies were given until Jan. 1, 1921, to install fume-, gas- and stench-consuming devices in their plants, and shortly after that date the chief engineer of the New York State Department of Health made an investigation.

The General Chemical Co. had been accumulating residues from the distillation of acetic acid. These had been stored in tanks and had been covered with ashes in order to prevent the diffusion of the fumes. The Barrett Co. operates a felt saturating machine on its property and has now installed hoods over the machines so that the fumes may be led to a scrubber. The Corn Products Refining Co. has on its premises a corn-grinding plant, and it proposes to lead the fumes from the grinding mill under the boilers so that they may be consumed. It was found necessary to line the flues with Monel metal, as all other linings were corroded by the fumes. The Spencer Kellogg Co. has on its property a plant for boiling or "aging" linseed oil. Experiments have been conducted in leading the vapors through or over slaked lime; they were also led through a scrubber. More recently the company has planned to lead the fume under the boilers and the tall smokestack so that they may be burned.

As all the defendants had shown a sincere desire to overcome the objections, they were given until March 19 to complete their fume-consuming devices. On that date a final hearing will be held in the New York Academy of Medicine. The interests of the city were looked after by Russell Tarbox, of the office of the Corporation Counsel, while the citizens' association was represented by W. H. Page.

The chemical plants involved in this complaint are all located at Shadyside-Edgewater (Bergen County), N. J., on the Hudson River opposite 125th St., New York.

Importance of Scientific Research

Saturday noon, Jan. 29, Dr. C. E. K. Mees, director of the Research Laboratory, Eastman Kodak Co., lectured before the City Club of Rochester on the importance of scientific research. The speaker pointed out the great advance in comfort and in the standard of living which had taken place in the last hundred years. This does not necessarily carry happiness with it; happiness comes from the spirit, but in material comfort, in material wealth, great progress has been made.

This gain in comfort and safety and wealth has come from the accumulated knowledge which is used by the technical men to produce at relatively low cost the roads and the railroads, the windows and the heating, the improved houses and the better food distribution.

The knowledge used by the technical men is applied science, and the science that is applied was made in the laboratories. Cheap glass came from the chemical laboratory in its final origin; it cannot be made without cheap alkali, and cheap alkali could not be made without an understanding of the chemistry of the alkaline metals which were first discovered by Humphry Davy. Electricity, which

plays so great a part in modern life, is generated by the rotation of wire coils in a magnetic field, and it was Faraday in his laboratory who first found that electricity could be produced in this way. All war waged on disease is based on the knowledge that disease is produced by micro-organisms, and the existence of these micro-organisms was discovered by Pasteur; so that the history of every advance is that there is first a discovery in a laboratory, and then other discoveries are made which extend and parallel it, and then it is developed in its own and other laboratories, and then it is applied experimentally, and finally there comes the industrial development of its application. Each step involves the introduction of other knowledge from the common stock of knowledge—sometimes other parts of the same science, sometimes knowledge from another science. Modern industry, then, and all modern civilization are built on science.

If the standard of comfort is to be further increased in the future the most obvious thing to do is to use the means that have proved successful in the past and to attempt by the development of more knowledge to gain more wealth. The inventions which have been made in recent years, especially in the field of electricity, show what could be done in this direction. Vast savings have been made by the development of improved electric lamps and refined and cheapened methods for telephones and telegraph transmission. The great electric companies are spending millions on scientific research, but the speaker believes that the application of research on a large scale to industry has only just begun and may easily be extended enormously.

The greatest field for research is in directions which seem at first sight to offer no prospect of immediate profit. The X-ray was discovered in the course of an investigation of some very obscure actions of minerals on photographic plates. One of the greatest discoveries in lighting technique came during a study of the absorption of gases in an evacuated lamp. A study of the emission of electric corpuscles from a hot wire produced the new types of waves which are so important in connection with wireless. It is possible that by a study of the chemical atom and of the way in which it breaks up in certain cases it may be possible to produce artificially the breaking down of atoms and thus to get power from their disintegration which would far transcend anything that has been available before. Should this prove successful its possibilities for industrial and social development would be limitless.

"Journal of Electricity and Western Industry"

Enlargement of the editorial scope of the *Journal of Electricity* and a change in its name to *Journal of Electricity and Western Industry* were announced at a dinner given on Feb. 1 in the Palace Hotel, San Francisco. The date marked the thirty-fifth anniversary of the *Journal of Electricity*, which has been one of the McGraw-Hill publications since September, 1919. Robert Sibley will continue as editor of the enlarged paper.

The *Journal of Electricity and Western Industry* will devoted to the upbuilding of the West as an industrial section, and it will interpret Western progress through the application of electric power, light and heat in industries and homes. In its enlarged scope the publication will record the progress of the far West not only of the electrical industry as such but also of all industry dependent upon electrical energy. The fullest editorial support will be given to financing the huge building programs of the Western electrical utilities in the development of hydro-electric power, as this is held to be the greatest single asset of the West.

Another Big Refinery for Wood River, Ill

The Wilcox Oil & Gas Corporation, of Tulsa, Okla., plans the erection of a large oil refinery at Wood River, Ill. H. F. Wilcox, president of the corporation, announces that the refinery will have a capacity of 20,000 bbl. and will be connected with the mid-continent fields by a pipe line. The Standard Oil and Roxana Petroleum companies already have refineries at Wood River, and the Empire Refineries, Inc., has more than 400 acres there for a similar purpose.

Trade Trip to Caribbean Ports

A formal call to commercial and financial institutions in the Central West to join in the trade schools to the West Indies and Central America has been issued by the Mississippi Valley Association, Harry H. Merrick, president. The cruise will start March 12 from New Orleans and will occupy a term of three weeks in visiting Caribbean points.

Personal

A. E. ANDERSON, general manager of the Ivorydale plant of the Procter & Gamble Co. at Cincinnati, Ohio, was elected a vice-president and is succeeded by FRANK K. SKILLMAN as general factory superintendent. Mr. Skillman served the company in various positions for over eighteen years at the Port Ivory and Kansas City plants.

WALTER BENEKE has resigned his position as instructor of chemistry at Cooper Union to accept a position as chemist with the Monsanto Chemical Works, St. Louis, Mo. Prior to his connection with Cooper Union Mr. Beneke was with the Organic Salt & Acid Co. of Newark, N. J.

Colonel G. A. BURRELL has returned to New York City after spending three months in Europe investigating matters relating to petroleum.

JOHN DISARIO, chemist and metallurgist, is now in charge of the laboratory, electric furnace and heat-treating of the Joliet Casting & Forgings, Ltd., Joliet, Que.

Major R. C. DITTO has been transferred from the Infantry to the Chemical Warfare Service.

W. A. DUNKLEY, who has been a gas engineer on the staff of the Illinois State Geological Survey, has accepted a position with the U. S. Bureau of Mines and will be acting in charge of the Urbana Station of the Bureau. Mr. Dunkley will continue there the work on fuels processing with which he has been associated for some years past.

Dr. OTTO KRESS, for the past four years in charge of the pulp and paper work at the Forest Products Laboratory at Madison, Wis., left Jan. 25 to join the staff of the Consolidated Water Power & Paper Co., at Appleton, Wis. He will be engaged with technical problems in connection with the control and development of pulp and paper products. Dr. Kress graduated as doctor of philosophy and chemistry at Columbia University in 1909 and engaged in pulp and paper mill work with various companies, joining the Bachische Co., New York City, in 1912, where he remained until he took charge of the work at Forest Products Laboratory. He is one of the founders of the Technical Association of the American Pulp and Paper Industry.

R. B. LADOO, a mineral technologist on the staff of the Bureau of Mines, is inspecting deposits of non-metals in the South.

D. A. LYON, chief metallurgist, E. A. HOLBROOK, chief metal mining engineer, and H. E. MYER, chief clerk, of the U. S. Bureau of Mines, are in Berkeley attending a conference of the superintendents of the Bureau's Western experiment stations and the deans of the various mining schools with which the Bureau is co-operating.

Major C. W. MASON has been transferred from the Infantry to the Chemical Warfare Service. He will be assigned to the command of a battalion of gas troops at Lakehurst.

W. W. ODELL, who has been conducting fuels carbonization investigation at the Urbana Station of the U. S. Bureau of Mines, has been transferred to the Washington offices, where he will assist in lignite carbonization studies.

W. R. SMITH, professor of chemistry, Lewis Institute, Chicago, spoke before the Chicago Chemists' Club recently on "Why I Believe in Ions."

W. M. WEIGEL, a mining engineer who has been in the employ of the Missouri Cobalt Co., has been employed by the Bureau of Mines to specialize in non-metallic matters. He will be stationed at Tuscaloosa, Ala.

Current Market Reports

The Chemical and Allied Industrial Market

NEW YORK, Feb. 7, 1921.

Although numerous inquiries for various chemicals reached the market during the past week, actual business was not large and transactions were confined mostly to small lot trading. It is believed that the steady expansion in inquiries is a forerunner to an increase in business. The acute declining tendency of the market during the past few months, however, has created a feeling of extreme conservatism among the domestic consumers, and the apparent disposition is to operate for the present on a hand-to-mouth basis.

Speculative interests have gradually got out of the market and those close to the pulse of trading assert that conditions will be more normal by spring.

Prices on *solid caustic soda* have not varied materially during the week. It seems reasonable that as soon as resale spot supplies are exhausted, producers will come into their own in both caustic and soda ash. The general quotation heard in leading quarters ranged from \$3.85@ \$3.95 per 100 lb. Moderate resale lots of *soda ash* in single bags were offered at \$2.10 per 100 lb., spot New York. The movement in this commodity was quiet throughout the week, with the tone, however, quite steady. Odd lots of imported *chlorate of potash* are on the market at very attractive prices. Some are of the opinion that the supply is relatively small and that a few good buying orders will probably clean up stocks. Quotations in the local market are heard from 8@18c. per lb., depending upon the brand, quantity and seller. The inside figure is for foreign material, while the outside price is named by leading producers f.o.b. works. It is stated that a few large orders are in the hands of exporters, but the wide variance in prices has retarded any actual business.

Moderate quantities of resale *bichromate of soda* continued to reach the market at 8½@8¾c. per lb. Reports were current that slightly under this could be done in some quarters on firm business, but dealers in general were not inclined to shade the inside price. Second hands quoted March shipments at 9@9½c. per lb. Demand for *salt cake* seems to be holding well, with some export business noted. With glass manufacturers ready to resume more normal operations, the outlook for this commodity seems bright and prices are expected to strengthen materially. Quotations on spot range from \$33@ \$35 per ton in bulk. Lower prices on *nitrate of potash* have been established by leading producers. The extreme range for pure double refined extends from 9½@12c. per lb., depending upon the grade and quantity. The inside price is for double bags of granulated and the outside figure for barrels of large crystals.

Lower prices are now effective for the different grades of refined *sulphur*. Sulphur flour, 100 per cent, pure sublimed, is offered at \$2.50@ \$3 per 100 lb. in barrels. Bags are obtainable at \$2.25@ \$2.75 per 100 lb., depending upon quantity. Sulphur roll, 100 per cent pure, ranges from \$2@ \$2.70 per 100 lb., depending upon containers and quantity. Moderate quantities of resale *bleaching powder* were offered by second hands at 2¾c. per lb. in large drums f.o.b. Niagara Falls. Spot material was quoted at 3c. per lb. The market looked quite steady, with a marked improvement in inquiries and orders.

COAL-TAR PRODUCTS

While business in general in the coal-tar products market has been on a limited scale throughout the week, the tone has shown considerable improvement. Color manufacturers have not changed their attitude in regard to prices and the quotations heard at the beginning of the week were largely in force at the close. Good reports from various mills keep coming in showing a resumption in operations, with full time in some quarters. Resale lots of intermediates, while mostly in small quantities, are again a little more freely

offered. The crude market is showing somewhat more activity on some items, while others are still quiet.

Benzene is moving in better volume and prices continue steady around 30@36c. per gal. The consuming demand for *anthracene* is improving, but the supply is limited. Producers of prime white *naphthalene* flakes are firm in their prices at 9@10c. per lb., while resale lots are heard in various directions at 8@8½c. per lb. Producers' prices on U.S.P. *salicylic acid* are quoted around 27@30c. per lb. Business has been very limited of late, owing to the lack of interest shown by domestic consumers. Prices on *aniline oil* on spot are rather weak at 21@21½c. per lb. Producers' prices are still at variance and range from 23@28c. per lb. Resale lots are plentiful on the market and in more or less distress. Second hand lots of *beta naphthol*, technical, could be had in good volume at 30c. per lb., although sales have been made during the week as low as 28c. Producers are holding their prices up around 40@45c. per lb., although in some quarters contracts have been offered at 35c. The market is very much disturbed and buyers are entering bids at figures well below the market price.

Prices on *dimethylaniline* are generally unsteady, although somewhat firmer than last week. Offers are heard at 55c. per lb. in the resale market, while some holders are asking as high as 65c. Little business is being transacted and consumers seem unwilling to come into the market in spite of the comparatively low price. Second-hand lots of *diphenylamine* are offered in several directions at prices well below the cost to manufacture. Offers are made at 60c. per lb., but it is quite well understood that this figure could be shaded in the face of firm business. Producers are naming prices around 70@75c. per lb., according to quantity. Manufacturers' figures on *paranitraniline* are given around \$1@1.05 per lb. Reports are still current, however, that odd lots are being held down to 90c. per lb. in several quarters. In the absence of firm business it has been impossible to determine what is the actual market value.

A wide difference exists between producers' prices and the resale market on *paratoluidine*. Offers have been heard as low as \$1.25 per lb., while one producer is still quoting as high as \$1.60. The general quotation ranged from \$1.30@1.40 per lb. The consuming demand for *beta naphthylamine* continued of a moderate routine nature. Producers in some quarters say they are better able to supply regular quantities, and quote the sublime variety at \$2.25@2.40 per lb. Spot stocks of *phenol* are comparatively low and prices are holding fairly well around 10@11c. per lb. The inquiry has been very dull and actual sales were few. In view of the present scarcity of spot material any considerable amount of business would probably force prices up further. There seems to be little inclination, however, for the consuming trade to enter the market to any extent.

The Chicago Market

CHICAGO, Feb. 4, 1921.

Steady progress in the return to a solid price basis was marked by new contract figures on *soda ash* and *caustic soda*. *Soda ash*, previously quoted at \$1.82½@1.90 per 100 lb. for 48 per cent f.o.b. works, is now priced \$1.72½@1.75. This quotation is for carload quantities. *Caustic*, 60 per cent base, in car f.o.b. works is now \$3.50@3.60 per 100 lb., which is about 15c. under previous offerings. A good business is being maintained and present price seems firm. *Bleaching powder*, quoted on contracts at 3½c. per lb., is reported as selling as low as 2½c. from second hands, spot demand being weak. Little interest is seen in *sal soda*, prices ranging from \$2@2.50 per 100 lb. out of local stock.

Barium chloride, in ample supply at \$85@90 per ton, seems to be getting topheavy from a recent influx of imported stock, and lower prices are looked for. *Bichromate of soda*, more plentiful in supply and weak in demand, is quoted at 9½c. per lb. from spot stock. *Soda cyanide* remains in short supply and the price is firm at 35c. per lb. *Soda prussiate* is weak, quotations ranging from 18@20c. per lb. Slackness in *glycerine* trade continues, with current quotation on c.p. grade being 20c. per lb., with but few transactions recorded.

Trading in *alcohol* is quiet, stocks being larger than seems justified by demand. The *ethyl* grade, 190 proof, is \$5.10@5.35 per gal.; *methyl* grade, 95 per cent, \$1.28@1.32 per gal.; *denatured*, complete, 75@80c. per gal. *Formaldehyde* remains down around 20@21c. per lb., with consumption slow.

VEGETABLE OILS

Declines have been noted in the entire line of vegetable oils during the past few weeks. Interest is lacking in crude *cottonseed oil*, offered for prompt shipment at 6c. per lb. f.o.b. valley. Texas offerings are 5½c. per lb. Large lots of Manila grade *coconut oil* changed hands last week at 8½c. per lb. in buyers' tanks f.o.b. Coast. This is nearly 1c. off former pricings. Ceylon grade is offered on the Coast at 9½c. per lb. *Corn oil*, diminished in supply and still in weak demand, is offered for February delivery in sellers' tanks at 6½c. f.o.b. Chicago. *Soya bean oil*, also in poor demand, is nominally 10½@11c. per lb. for edible grade, in Chicago stock. Inactivity in consuming industries is causing this market to continue weak on all items.

COAL-TAR PRODUCTS

The market for crudes is in a little better shape except in the case of *naphthalene*, which is still plentiful on the spot. Flakes are quoted at 9@10c. per lb. and balls at 10@11c., but it is reported that bone fide orders would produce sharp shading. *Benzene*, water white grade, is 33@33½c. per gal., and reports are heard of limited transactions at a lower figure. *Solvent naphtha* is weak in demand, water white grade being quoted at 28@30c. per gal. and crude at 16@19c.

Among the intermediates, *aniline oil* and *aniline salt* are representative. In the face of numerous inquiries the price is off, the oil being offered at 29@30c. per lb. by producers and down as low as 22c. by second hands. The salt is a little firmer, 29@32c. being the quoted range, with some business done at the lower figure. *Benzyl chloride* is subject to lively inquiry and the current quotation is around 28c. on the 95 per cent and 23c. on the crude.

The St. Louis Market

ST. LOUIS, Feb. 4, 1921.

The feeling of cheerfulness reported two weeks ago has spread until heavy chemical producers are looking forward to a resumption of a fair amount of activity during the month of February. This optimistic mood of producers is being backed up to some extent by buyers. One of the largest producers reports that orders are coming better at present than at any time during the last forty days and that shipments scheduled for February will be considerably higher than those for January. It is admitted, however, that even with the present increase in sales the market would be characterized as somewhat slow during normal times.

The 98 deg. *sulphuric acid* is being shipped in fair amounts on a quotation of \$24 per ton f.o.b. works. The market for the 66 deg. *sulphuric acid* has held up well during the past two weeks, the demand being fairly strong, and the price remaining unchanged at \$20@21 per ton and 1½c. per lb. in carboys. The demand for the 60 deg. *sulphuric acid* is quiet. It is being quoted at \$16 per ton and 1½c. per lb. in carboys. Inquiries for *oleum* continue good, with sales bettering somewhat. Producers are asking \$28.50 per ton.

Muriatic acid is showing flashes of activity and production has increased somewhat. Current quotations are 1½@2c. per lb. in carboys and \$25 per ton in bulk.

The demand for *sodium bisulphate* has slowed down to a very conservative level once more, though shipments on contract are holding up well. It is being quoted at \$7 to \$8 per ton.

Nitric acid is in better demand with prices at the same level as they were two weeks ago. Quotations are \$7 per 100 lb. for the 36 deg. test and \$10 per 100 lb. for the 42 deg. Standard mixed acid is unchanged in price from its quotation of two weeks ago, 1½c. per lb. of sulphuric content and 11½c. per lb. of nitric content.

The Iron and Steel Market

PITTSBURGH, Pa., Feb. 4, 1921.

The stagnation in the iron and steel market is even more pronounced than at any previous time in this depression. That, however, is what should have been expected, since there has been no such change in fundamental economic or financial conditions as would produce an improvement.

Readjustment in commodity prices and wage rates is by no means completed, if indeed it is more than well begun. As to financial conditions, if the operation of the Federal Reserve banking system prevented the development of a panic or financial crisis, then the fundamental conditions that usually cause such a phenomenon must have been present and their other results must be expected. The steel industry has noticed recently a great slowing down in payments in some quarters, and as it normally does a cash business, this is a suggestive symptom.

The rate of pig iron production by merchant furnaces and independent steel works furnaces has continued to decrease. Taking the iron and steel industry as a whole and considering the high operating rate of the Steel Corporation on the one hand and the low operating rate of the independent steel works and the merchant blast furnaces on the other, the rate of production in both pig iron and steel ingots is now approximately 60 per cent of actual productive capacity.

STEEL PRICES

While there are many rumors in circulation of cut prices being made, that is, as noted in last report, really a psychological phenomenon always observed in the steel industry in a time of depression. In previous periods most of the rumors proved unfounded, and that is the case now. With the exception of plates, steel prices in general are being very well held indeed. As to plates, the market should be quoted at 2.50c. rather than at the Industrial Board price of 2.65c. There is no question that plates have been and can be bought at 2.50c., although not only the Steel Corporation but several independents are rigidly adhering to the 2.65c. figure. Otherwise the market remains quotable at Industrial Board prices: Bars, 2.35c.; shapes, 2.45c.; blue annealed sheets, 3.55c.; black sheets, 4.35c.; galvanized sheets, 5.70c.; plain wire, 3.25c.; wire nails, \$3.25; standard steel pipe, 57½ per cent basing discount; hoops, 3.05c.; tin plate, \$7 per base box, 100 lb. The tin plate quotation is on "production plates." Mills having odd lots in stock would probably sell such material at the usual concessions, and there are stocks held by middle interests, chiefly intended originally for export, that can be picked up at \$6 or less by those who are content to take misfit sizes.

Nuts and bolts, reduced last week by fully 20 per cent, following other reductions last year, have been quite steady, although not in good demand. They may be regarded as one of the manufactures of steel that have been fully adjusted down to the mill prices now ruling for their raw material. Rivets are 4c. and railroad spikes 3.65c., prices that suggest need of further revision. This week the base price of chain was reduced from 7.25c. to 6.75c., while the differentials for smaller sizes were reduced, whereby some sizes are reduced altogether by 1c. and others by 1.25c. The war control price was 7.50c., the lowest price since then, during the second half of 1919, having been 5.75c. The quoted price refers to 1-in. proof coil chain.

PIG IRON

There have been offerings of foundry iron by producers on the basis of \$29, valley basis, or \$1 under what was previously quotable as the market, but buyers show no interest in this price and no disposition to suggest a price in which they would be interested. Bessemer and basic remain quotable at \$32 and \$30 respectively, but these prices are altogether nominal, subject to revision by furnaces in case any disposition is shown to buy even a moderate sized tonnage. At the meeting of the American Pig Iron Association stocks in merchant furnace yards were reported as slightly under 400,000 tons, and undelivered tonnage on books 1,500,000 tons, equal to about seven weeks of production at a fairly full rate or four months at present rate.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

	Carlots	Less Carlots
Acetic anhydride.....lb.	\$0.13 - \$0.13½	\$0.55 - \$0.60
Acetone.....lb.	1.34 - 1.4	1.34 - 1.4

Blue vitriol (see copper sulphate).....lb.	04½ - 05	05½ - 06
Borax (see sodium borate).....lb.	04½ - 05	05½ - 06
Brimstone (see sulphur, roll).....lb.	50 - 52	54 - 56
Bromine.....lb.	2.00 - 2.05	2.00 - 2.05
Calcium acetate.....100 lbs.	04 - 04½	04½ - 05
Calcium carbide.....lb.	27.00 - 29.00	30.00 - 32.00
Calcium chloride, fused, lump.....ton	01½ - 02	02½ - 03
Calcium chloride, granulated.....lb.	02½ - 03	03½ - 04
Calcium hypochlorite (bleaching powder).....lb.	1.25 - 1.30	1.25 - 1.30
Calcium peroxide.....lb.	16 - 18	16 - 18
Calcium phosphate, monobasic.....lb.	80 - 85	80 - 85
Camphor.....lb.	08 - 08½	09 - 09½
Carbon bisulphide.....lb.	12 - 12½	13 - 13½
Carbon tetrachloride, drums.....lb.	75 - 1.00	75 - 1.00
Carbonyl chloride (phosgene).....lb.	09 - 09½	10 - 10½
Caustic potash (see potassium hydroxide).....lb.	43 - 50	43 - 50
Caustic soda (see sodium hydroxide).....lb.	3.10 - 3.20	3.10 - 3.20
Chlorine, gas, liquid-cylinders (100 lb.).....lb.	22 - 22½	24 - 25
Chloroform.....lb.	06½ - 06½	06½ - 07½
Cobalt oxide.....lb.	06½ - 06½	06½ - 07½
Copperas (see iron sulphate).....lb.	06½ - 06½	06½ - 07½
Copper carbonate, green precipitate.....lb.	06½ - 06½	06½ - 07½
Copper cyanide.....lb.	06½ - 06½	06½ - 07½
Copper sulphate, crystals.....lb.	06½ - 06½	06½ - 07½
Cream of tartar (see potassium bitartrate).....lb.	06½ - 06½	06½ - 07½
Epsom salt (see magnesium sulphate).....lb.	06½ - 06½	06½ - 07½
Ethyl Acetate Com. 85%.....gal.	1.05 - 1.10	1.05 - 1.10
Ethyl Acetate pure (acetic ether 98% to 100%).....gal.	1.18 - 1.18½	1.18 - 1.19
Formaldehyde, 40 per cent.....lb.	3.50 - 3.60	3.50 - 3.60
Fusel oil, ref.....gal.	2.75 - 3.00	2.75 - 3.00
Fusel oil, crude.....gal.	2.75 - 3.00	2.75 - 3.00
Glauber's salt (see sodium sulphate).....lb.	20 - 21	20 - 21
Glycerine, C. P. drums extra.....lb.	3.85 - 4.00	3.85 - 4.00
Iodine, resublimed.....lb.	10 - 20	10 - 20
Iron oxide, red.....lb.	1.25 - 1.50	1.75 - 2.00
Iron sulphate (copperas).....100 lb.	14½ - 16	14½ - 16
Lead acetate, normal.....lb.	11 - 12	12½ - 13
Lead arsenate (paste).....lb.	11 - 12	12½ - 13
Lead nitrate.....lb.	15 - 20	15 - 20
Litharge.....lb.	08½ - 09	09½ - 10
Lithium carbonate.....lb.	10½ - 11	11½ - 12
Magnesium carbonate, technical.....lb.	2.50 - 3.00	2.50 - 3.00
Magnesium sulphate, U. S. P.....190 lb.	1.50 - 1.75	1.50 - 1.75
Magnesium sulphate, commercial.....190 lb.	1.30 - 1.40	1.30 - 1.40
Methanol, 95%.....gal.	1.50 - 1.60	1.50 - 1.60
Methanol, pure.....gal.	1.2 - 1.2½	1.2 - 1.2½
Nickel salt, double.....lb.	13 - 13½	13 - 13½
Nickel salt, single.....lb.	13 - 13½	13 - 13½
Phosgene (see carbonyl chloride).....lb.	45 - 46	47 - 50
Phosphorus, red.....lb.	45 - 46	47 - 50
Phosphorus, yellow.....lb.	14½ - 14½	15 - 15½
Potassium bichromate.....lb.	14½ - 14½	15 - 15½

		Carlots	Less Carlots
Potassium bitartrate (cream of tartar).....	lb.	\$.33 — .35	\$0.33 — \$0.35
Potassium bromide, granular.....	lb.	.20 — .40	.20 — .40
Potassium carbonate, U. S. P.....	lb.	.35 — .40	.45 — .50
Potassium carbonate, crude.....	lb.	.11 — .11½	.11 — .12
Potassium chlorate, crystals.....	lb.	.08 — .10	.11 — .18
Potassium cyanide.....	lb.	.65 — .70	.65 — .70
Potassium hydroxide (caustic potash).....	lb.	.14 — .14½	.15 — .16
Potassium muriate.....	ton	75.00 — 80.00	
Potassium iodide.....	lb.		3.00 — 3.20
Potassium nitrate.....	lb.	.09½ — .10	.10 — .12½
Potassium permanganate.....	lb.	.48 — .50	.52 — .60
Potassium prussiate, red.....	lb.	.50 — .52	.53 — .55
Potassium prussiate, yellow.....	lb.	.26 — .26½	.27 — .27½
Potassium sulphate (powdered).....	per uni		— 2.25
Rochelle salts (see sodium potas tartrate).....			
Salammoniac (see ammonium chloride).....			
Sal soda (see sodium carbonate).....			
Salt cake.....	ton		33.00 — 35.00
Silver cyanide.....	oz.		1.25 —
Silver nitrate.....	oz.		.43 — .44
Soda ash, light.....	100 lb.	2.10 — 2.15	2.20 — 2.30
Soda ash, dense.....	100 lb.	2.20 — 2.25	2.30 — 2.50
Sodium acetate.....	lb.	.05½ — .05½	.06 — .06½
Sodium bicarbonate.....	100 lb.	2.50 — 2.75	3.00 — 3.25
Sodium bichromate.....	lb.	.08½ — .08½	.08½ — .09
Sodium bisulphate (nitre cake).....	ton	7.00 — 7.50	8.00 — 11.00
Sodium bisulphite powdered, U.S.P.....	lb.	.06½ — .06½	.06½ — .07½
Sodium borate (borax).....	lb.	.07 — .07½	.07½ — .08
Sodium carbonate (sal soda).....	100 lb.	2.00 — 2.25	2.50 — 2.75
Sodium chl rate.....	lb.	.10 — .10½	.10½ — .11
Sodium cyanide, 96-98 per cent.....	lb.	.20 — .21	.22 — .28
Sodium fluoride.....	lb.	.13 — .14	.14½ — .15
Sodium hydroxide (caustic soda).....	100 lb.	3.85 — 3.90	3.95 — 4.25
Sodium hyposulphite.....	lb.		.03½ — .04
Sodium nitrate.....	100 lb.	2.85 —	3.00 —
Sodium nitrite.....	lb.	.06 — .06½	.06½ — .07
Sodium peroxide, powdered.....	lb.	.30 — .31	.32 — .34
Sodium phosphate, dibasic.....	lb.	.03½ — .04½	.04½ — .05
Sodium potassium tartrate (Rochelle salts).....	lb.		.31 — .32
Sodium prussiate, yellow.....	lb.	.16½ — .17	.17½ — .17½
Sodium silicate, solution (40 deg.).....	lb.	.01½ — .01½	.02 — .02½
Sodium silicate, solution (60 deg.).....	lb.	.03 — .03½	.03½ — .04
Sodium sulphate, crystals (Glauber's salt).....	100 lbs.	1.75 — 2.00	2.25 — 2.50
Sodium sulphide, crystal, 60-62 per cent (conc.).....	lb.	.05 — .05½	.05½ — .06
Sodium sulphite, crystals.....	lb.	.04 — .04½	.04½ — .05
Strontium nitrate, powdered.....	lb.	.17½ — .18	.18½ — .18½
Sulphur chl ride, red.....	lb.	.07 — .07½	.07½ — .08
Sulphur, crude.....	ton	16.00 — 18.00	
Sulphur dioxide, liquid, cylinders.....	lb.	.08 — .08½	.08½ — .09
Sulphur (sublimed), flour.....	100 lb.		2.25 — 3.10
Sulphur, roll (brimstone).....	100 lb.		2.00 — 2.75
Tin bichloride, 50 per cent.....	lb.	.18 — .19	
Tin oxide.....	lb.		.48 — .50
Zinc carbonate, precipitate.....	lb.	.16 — .18	.19 — .20
Zinc chloride, gran.....	lb.	.11½ — .12	.12½ — .13
Zinc cyanide.....	lb.	.45 — .49	.50 — .60
Zinc dust.....	lb.	.12 — .13	.13½ — .14
Zinc oxide, XX.....	lb.	.08½ — .09	.09½ — .11
Zinc sulphate.....	lb.	.03½ — .03½	.04 — .06

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude.....	lb.	\$1.10 — \$1.15
Alpha-naphthol, refined.....	lb.	1.45 — 1.50
Alpha-naphthylamine.....	lb.	.38 — .40
Aniline oil, drums extra.....	lb.	.21 — .27
Aniline salts.....	lb.	.27 — .30
Anthracene, 80% in drums (100 lb.).....	lb.	.75 — 1.00
Benzaldehyde (f.f.c.).....	lb.	2.00 — 2.10
Benzidine, base.....	lb.	1.00 — 1.10
Benzidine sulphate.....	lb.	.80 — .90
Benzoic acid, U.S.P.....	lb.	.70 — .75
Benzoate of soda, U.S.P.....	lb.	.70 — .80
Benzene, pure, water-white, in drums (100 gal.).....	gal.	.30 — .35
Benzene, 90% in drums (100 gal.).....	gal.	.28 — .32
Benzyl chloride, 95-97%, refined.....	lb.	.30 — .35
Benzyl chloride, tech.....	lb.	.25 — .30
Beta-naphthol benzoate.....	lb.	3.50 — 4.00
Beta-naphthol, sublimed.....	lb.	.75 — .80
Beta-naphthol, tech.....	lb.	.30 — .35
Beta-naphthylamine, sublimed.....	lb.	2.25 — 2.40
Cresol, U. S. P., in drums (100 lb.).....	lb.	.16 — .18
Ortho-cresol, in drums (100 lb.).....	lb.	.23 — .25
Cresylic acid, 97-99%, straw color, in drums.....	gal.	.95 — 1.00
Cresylic acid, 75-97%, dark, in drums.....	gal.	.90 — .95
Cresylic acid, 50%, first quality, drums.....	gal.	.65 — .75
Dichlorobenzene.....	lb.	.06 — .09
Diethylaniline.....	lb.	1.25 — 1.30
Dimethylaniline.....	lb.	.55 — .65
Dinitrobenzene.....	lb.	.30 — .32
Dinitrochlorobenzene.....	lb.	.25 — .30
Dinitronaphthalene.....	lb.	.33 — .35
Dinitrophenol.....	lb.	.40 — .45
Dinitrotoluene.....	lb.	.25 — .30
Dip oil, 25%, tar acids, car lots, in drums.....	gal.	.37 — .40
Diphenylamine.....	lb.	.60 — .70
H-acid.....	lb.	1.30 — 1.50
Meta-phenylenediamine.....	lb.	1.25 — 1.30
Monochlorobenzene.....	lb.	.14 — .16
Monoethylaniline.....	lb.	2.00 — 2.10
Naphthalene crushed, in bbls. (250 lb.).....	lb.	.08 — .08½
Naphthalene, flake.....	lb.	.08 — .08½
Naphthalene, balls.....	lb.	.09 — .09½
Naphthionic acid, crude.....	lb.	.70 — .75
Nitrobenzene.....	lb.	.12 — .15
Nitro-naphthalene.....	lb.	.30 — .35
Nitro-toluene.....	lb.	.18 — .25
Ortho-amidophenol.....	lb.	3.20 — 3.75
Ortho-dichlorobenzene.....	lb.	.15 — .20
Ortho-nitro-phenol.....	lb.	.75 — .80
Ortho-nitro-toluene.....	lb.	.22 — .24
Ortho-toluidine.....	lb.	.25 — .30
Para-amidophenol, base.....	lb.	1.90 — 2.0
Para-amidophenol, HCl.....	lb.	2.10 — 2.20

Para-dichlorobenzene.....	lb.	.15 — .25
Paranitroaniline.....	lb.	.90 — .95
Para-nitrotoluene.....	lb.	.90 — 1.05
Para-phenylenediamine.....	lb.	1.80 — 2.20
Para-toluidine.....	lb.	1.30 — 1.60
Phthalic anhydride.....	lb.	.55 — .60
Phenol, U. S. P., drums (dest.), (240 lb.).....	lb.	.10 — .12
Pyridine.....	gal.	2.00 — 3.50
Resorcinol, technical.....	lb.	1.85 — 2.00
Resorcinol, pure.....	lb.	2.75 — 3.00
Salicylic acid, tech., in bbls. (110 lb.).....	lb.	.23 — .25
Salicylic acid, U. S. P.....	lb.	.27 — .30
Salol.....	lb.	.85 — .95
Solvent naphtha, water-white, in drums, 100 gal.....	gal.	.28 — .32
Solvent naphtha, crude, heavy, in drums, 100 gal.....	gal.	.16 — .18
Sulphanilic acid, crude.....	lb.	.30 — .35
Tolidine.....	lb.	1.40 — 1.60
Toluidine, mixed.....	lb.	.45 — .50
Toluene, in tank cars.....	gal.	.30 — .32
Toluene, in drums.....	gal.	.33 — .35
Xylidines, drums, 100 gal.....	lb.	.45 — .50
Xylene, pure, in drums.....	gal.	.42 — .45
Xylene, pure, in tank cars.....	gal.	.45 — .45
Xylene, commercial, in drums, 100 gal.....	gal.	.33 — .35
Xylene, commercial, in tank cars.....	gal.	.30 — .35

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark.....	lb.	\$0.24 — \$0.26
Beeswax, refined, light.....	lb.	.27 — .28
Beeswax, white pure.....	lb.	.40 — .45
Carnauba, No. 1.....	lb.	.75 — .80
Carnauba, No. 2, North Country.....	lb.	.35 — .40
Carnauba, No. 3, North Country.....	lb.	.18 — .19
Japan.....	lb.	.19 — .20
Montan, crude.....	lb.	.07 — .08
Paraffine waxes, crude match wax (white) 105-110 m.p.....	lb.	.04½ — .05½
Paraffine waxes, crude, scale 124-126 m.p.....	lb.	.04½ — .04½
Paraffine waxes, refined, 118-120 m.p.....	lb.	.06 — .06
Paraffine waxes, refined, 125 m.p.....	lb.	.06½ — .06½
Paraffine waxes, refined, 128-130 m.p.....	lb.	.07½ — .07½
Paraffine waxes, refined, 133-135 m.p.....	lb.	.08 — .08½
Paraffine waxes, refined, 135-137 m.p.....	lb.	.10 — .10
Stearic acid, single pressed.....	lb.	.12½ — .12½
Stearic acid, double pressed.....	lb.	.13½ — .13½
Stearic acid, triple pressed.....	lb.	.14 — .14

Flotation Oils

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr. 0.930-0.940.....	gal.	\$1.70
Pine oil, pure, dest. dist.....	gal.	1.60
Pine tar oil, ref., sp.gr. 1.025-1.035.....	gal.	.48
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.....	gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990.....	gal.	.75
Pine tar, ref., thin, sp.gr. 1.080-1.960.....	gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970.....	gal.	1.20
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990.....	gal.	.37
Pinewood creosote, ref.....	gal.	.55

Naval Stores

The following prices are f.o.b. New York for carload lots.

Rosin B-D, bbl.....	280 lb.	\$8.50 —
Rosin E-I.....	280 lb.	8.50 —
Rosin K-N.....	280 lb.	8.50 —
Rosin W. G.-W. W.....	280 lb.	8.75 —
Wood rosin, bbl.....	280 lb.	9.00 —
Spirits of turpentine.....	gal.	.65 —
Wood turpentine steam dist.....	gal.	.64 —
Wood turpentine, dest. dist.....	gal.	.63 —
Pine tar pitch, bbl.....	200 lb.	8.50 —
Tar, kiln burned, bbl. (500 lb.).....	bbl.	15.00 —
Retort tar, bbl.....	500 lb.	15.00 — 15.50
Rosin oil, first run.....	gal.	.52 —
Rosin oil, second run.....	gal.	.54 —
Rosin oil, third run.....	gal.	.62 —

Solvents

73-76 deg., steel bbls. (85 lb.).....	gal.	\$0.41
70-72 deg., steel bbls. (85 lb.).....	gal.	.39
68-70 deg., steel bbls. (85 lb.).....	gal.	.38
V. M. and P. naphtha, steel bbls. (85 lb.).....	gal.	.30

Crude Rubber

Para-Upriver fine.....	lb.	\$0.18½ — \$0.19
Upriver coarse.....	lb.	.14 — .14½
Upriver caucho ball.....	lb.	.14½ — .14½
Plantation—First latex crepe.....	lb.	.18½ —
Ribbed smoked sheets.....	lb.	.17½ —
Brown crepe, thin, clean.....	lb.	.18 —
Amber crepe No. 1.....	lb.	.20 —

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls.....	lb.	\$0.09 — \$0.10
Castor oil, AA, in bbls.....	lb.	.11 — .11½
China wood oil, in bbls. (f.o.b. Pac. coast).....	lb.	.08½ — .08½
Cocanut oil, Ceylon grade, in bbls.....	lb.	.12 — .12½
Cocanut oil, Cochin grade, in bbls.....	lb.	.12½ — .13
Corn oil, crude, in bbls.....	lb.	.08½ — .09
Cottonseed oil, crude (f. o. b. mill).....	lb.	.06 — .06½
Cottonseed oil, summer yellow.....	lb.	.08½ — .09
Cottonseed oil, winter yellow.....	lb.	.09 — .09½
Linseed oil, raw, car lots (domestic).....	gal.	.70 — .71
Linseed oil, raw, tank cars (domestic).....	gal.	.63 — .63
Linseed oil, boiled, car lots (domestic).....	gal.	.72 — .73

Olive oil, commercial.....	gal	\$2.25	—	\$2.40
Palm, Lagos.....	lb.	.07½	—	.07½
Palm, Niger.....	lb.	.07	—	.07½
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.06½	—	.07
Peanut oil, refined, in bbls.....	lb.	.13	—	.13½
Rapeseed oil, refined in bbls.....	gal.	1.10	—	1.15
Rapeseed oil, blown, in bbls.....	gal.	1.20	—	1.25
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.08	—	.08½
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.05½	—	

FISH

Light pressed menhaden.....	gal.	\$0.48	—	\$0.50
Yellow bleached menhaden.....	gal.	.50	—	.52
White bleached menhaden.....	gal.	.52	—	.54
Blown menhaden.....	gal.	.88	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	22.00	—	26.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	—	17.00
Barytes, floated, f.o.b. St. Louis.....	net ton	26.50	—	28.00
Barytes, crude, first grade, Missouri.....	net ton	10.00	—	
Blanc fixe, dry.....	lb.	.05	—	.05½
Blanc fixe, pulp.....	net ton	50.00	—	60.00
Casein.....	lb.	.14	—	.18
Chalk, domestic, extra light.....	lb.	.05	—	.06
Chalk, domestic, light.....	lb.	.04½	—	.05½
Chalk, domestic, heavy.....	lb.	.04	—	.05
Chalk, English, extra light.....	lb.	.05	—	.07
Chalk, English, light.....	lb.	.05	—	.06
Chalk, English, dense.....	lb.	.04½	—	.05
China clay (kaolin) crude, f.o.b. mines, Georgia.....	net ton	8.00	—	10.00
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	12.00	—	15.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	18.00	—	22.00
China clay (kaolin) crude f.o.b. Virginia points.....	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	15.00	—	40.00
China clay (kaolin), imported, lump.....	net ton	25.00	—	35.00
China clay (kaolin), imported, powdered.....	net ton	30.00	—	35.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	gross ton	8.00	—	14.00
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mi es.....	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Fla.....	net ton	25.00	—	
Fullers earth, powdered, f.o.b. Fla.....	net ton	18.00	—	
Fullers earth, imported, powdered.....	net ton	35.00	—	40.00
Graphite, crucible, 90% carbon, Ashland, Ala.....	lb.	.07	—	.09
Graphite, crucible, 85% carbon, Ashland, Ala.....	lb.	.11	—	.40
Graphite, higher lubricating grades.....	lb.	.04	—	.50
Pumice stone, imported, lump.....	lb.	.06	—	
Pumice stone, domestic lump.....	lb.	.04	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore.....	net ton		—	10.00
Quartz (acid tower) 1½ @ 2 in., f.o.b. Baltimore.....	net ton		—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton		—	17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	—	7.50
Shellac, orange fine.....	lb.	.60	—	
Shellac, orange superfine.....	lb.	.70	—	
Shellac, A. C. garnet.....	lb.	.58	—	
Shellac, T. N.....	lb.	.55	—	
Soapstone.....	ton	15.00	—	25.00
Sodium chloride.....	long ton		—	17.50
Talc, paper-making grades, f.o.b. Vermont.....	ton	12.00	—	22.00
Talc, roofing grades, f.o.b. Vermont.....	ton	9.50	—	15.00

Plates, ½ to 1 in. thick.....	3.93	4.00	3.67	3.78	3.57	3.78	3.67

*Add 10c per 100 lb. for trucking to Jersey City and 15c for delivery in New York and Brooklyn

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Colorado

LA VETA—City had plans prepared for construction of sewerage system, including Inhoff tank, gravel bed filtration and chlorine plants. J. O. Francisco, engr.

Florida

KISSIMMEE—Tucker Brick Co. plans to rebuild brick plant which was recently destroyed by fire. Estimated cost, \$15,000.

Illinois

LITCHFIELD—City plans water-works improvements and construction of filtration plant. Estimated cost, \$200,000. J. W. Allen, City Hall, city clk.

Indiana

INDIANAPOLIS—C. & A. Potts & Co., 816 West Washington Ave., plans to build 1-story, brick and steel foundry on Blake St. Estimated cost, \$45,000. Architect not selected.

Iowa

BUFFALO CENTER—Consolidated School Dist. is having plans prepared for the construction of a 2-story, 82x145-ft. rein.-con. and brick high school here. A chemical laboratory will be installed in same. Estimated cost, \$150,000. G. L. Lockhart, 294 Endicott Bldg., St. Paul, Minn., archt.

OTTUMWA—The Bd. Educ. will receive bids until Feb. 23 for construction of a 3-story rein.-con. and brick high school. A chemical laboratory will be installed in same. Estimated cost, \$700,000. Croft & Boerner, 1006 Marquette Ave., Minneapolis, archts. Noted July 21.

UTE—C. W. Hitchen, city clk., will receive bids until Feb. 15 for the construction of about 19,000 lin.ft. vitr. pipe sewer, settling tank and twin filter beds. Estimated cost, \$50,000. E. E. Carlson, Battle Creek, engr.

Illinois

SPRINGFIELD—City Water Dept. plans to build water softening and iron removal plant. Estimated cost, \$75,000. Burns & McDonnell, 400 Interstate Bldg., Kansas City, Mo., engr.

Michigan

DETROIT—Park Davis & Co., Atwater St. and McDougall Ave., will soon award the contract for construction of a 7-story, 200x248-ft. brick, steel and rein.-con. factory. Smith, Hinchman & Grylls, 710 Washington Arcade, archts. Noted Jan. 19.

GRAND RAPIDS—City will receive bids about Feb. 15 for construction of a filtration plant. Estimated cost, \$400,000. R. E. Harrison, 1260 Nicholas Bldg., Toledo, engr.

Minnesota

COOKSTON—Miller Tanning Co., 615 Woodland Ave., having plans prepared for the construction of a 2-story, 50x50-ft. concrete tannery here. Estimated cost, \$13,000. E. T. Gillies, 248 McKnight Bldg., Minneapolis, engr.

MANKATO—The Immanuel Hospital Association is having plans prepared for construction of a 3-story rein.-con. and brick addition to hospital on Washington and Ford Sts. A clinical and pathological laboratory and X-ray department will be installed in same. Estimated cost, \$150,000. Schippel & Schmidt, Kruse Bldg., archts. Noted Dec. 8.

Ohio

CLEVELAND—Bd. Educ. is having plans prepared for the construction of a 3-story, brick and steel high school on East 116th St. and Corlett Ave. A chemical laboratory will be installed in same. Estimated cost, \$2,000,000. W. R. McCormack, East 6th St. and Rockwell Ave., archt.

CLEVELAND—Bd. Educ. is having plans prepared for the construction of a 2-story, brick and steel high school in Collinwood Dist. A chemical laboratory will be installed in same. Estimated cost, \$2,000,000. W. R. McCormack, East 6th St. and Rockwell Ave., archt.

GENEVA—Bd. Pub. Affairs will receive bids until Feb. 15 for enlarging and improving water filtration plant here, including construction of new filter plant with 1,000,000-gal. capacity. P. Burgess, 141 East Broad St., Columbus, engr.

GIBSONBURG—Kelly Island Lime & Transport Co., c/o J. A. Kling, pres., Leader-News Bldg., Cleveland, has awarded the contract for the construction of a 1-story, 50x130-ft. hydrating lime plant here, to Forst City Steel & Iron Works, 1500 West 110th St., Cleveland. Estimated cost, \$50,000.

NEWARK—Leonard Oil Gas Co. plans to build an oil refinery here. Rust Engr. Co., 1901 Fifth Ave., Pittsburgh, Pa., engr.

Oklahoma

MOUNTAIN VIEW—City is having preliminary plans prepared for construction of sewerage system and disposal plant. V. V. Long & Co., 1300 Colcord Bldg., Oklahoma City, engr.

Pennsylvania

READING—Bd. Educ. 8th and Washington Sts., plans to build 3-story, 300x300-ft. concrete high school. A chemical laboratory will be installed in same. Architect not selected.

South Dakota

ABERDEEN—Bd. Educ. receives bids about April 2 for construction of a 3-story, rein.-con. and brick high school. A chemical laboratory will be installed in same. Estimated cost, \$300,000. W. W. Beach Co., Sioux City, Iowa, archts.

BELLEFOURCHE—Bd. Educ. will soon receive bids on 42x60-ft. rein.-con. and brick first unit of a 2-story high school. A chemical laboratory will be installed in same. Estimated cost, \$100,000. W. W. Beach Co., Sioux City, archts.

Tennessee

ALTON PARK—The Du Bois Rubber Co., 315 Volunteer Bldg., let contract for the construction of a 2-story, 40x50-ft. rubber plant here, to Chickamauga Quarry & Constr. Co., Chickamauga. Estimated cost, \$100,000.

Texas

DALLAS—City plans the construction of a water purification plant, 15,000,000-gal. capacity. Estimated cost, \$500,000. G. D. Fairtrace, city engr.

GRAHAM—City plans to construct reservoir dam on Salt Creek, extend water mains, enlarge pumping plant and filtration bed and extend and enlarge sewage disposal plant. Estimated cost, \$100,000. H. E. Elrod Eng. Co., Interurban Bldg., Dallas, consult. engr.

TERRELL—City has awarded the contract for the construction of a pump house and filtration system, including oil engines and 2 pumps, to Mergle Machinery Co., Tulsa, Okla. Estimated cost, \$47,850.

WACO—Herring Ave. Methodist Church is having plans prepared for the construction of a 3-story, 75x100-ft. brick and concrete hospital on Herring Ave. A chemical laboratory will be installed in same. About \$100,000. R. H. Hunt Co., Southwest Life Bldg., Dallas, archts.

Wisconsin

KAUKAUNA—Molock Co. is in the market for brass foundry equipment, including ovens.

RACINE—Wisconsin Gas & Electric Co., Public Service Bldg., Milwaukee, has awarded the contract for the construction of a 2-story, 40x60-ft. brick and concrete gas plant addition to Bingard & Christianson, 2220 Kinzie Ave.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold annual meeting Feb. 21 to 24 at Columbus, Ohio, with headquarters at the Deschl Hotel.

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City, April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN ENGINEERING COUNCIL will meet at Syracuse, N. Y., Feb. 14 and 15.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its spring meeting June 20 to 24 at Detroit. Industrial excursion will be made to Ann Arbor, Saginaw, Michigan and Bay City.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting Feb. 14 to 17 in New York City.

AMERICAN OIL CHEMISTS' SOCIETY (formerly the Society of Cotton Product Analysts) will hold its twelfth annual meeting in Chicago May 16 and 17.

AMERICAN PAPER & PULP ASSOCIATION will hold its annual meeting at the Waldorf Astoria and Hotel Astor, New York City, April 11 to 15.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at the Congress Hotel, Chicago, May 23 to 26.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting at the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

CHAMBER OF COMMERCE OF THE UNITED STATES will hold its ninth annual meeting in Atlantic City April 27, 28 and 29.

NATIONAL PETROLEUM CONGRESS will meet at the Hotel Baltimore, Kansas City, Mo., March 22 to 25.

NEW JERSEY CHEMICAL SOCIETY holds meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

DR. EDGAR F. SMITH will address the joint gathering of the New York Section of the American Electrochemical Society and the American Chemical Society, and the American sections of the Society of Chemical Industry and the Société de Chimie Industrielle at the Chemists' Club on the evening of Feb. 11. His subject is "Research."

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: Feb. 11, American Electrochemical Society, joint meeting with Society of Chemical Industry, American Chemical Society and Société de Chimie Industrielle; March 11, American Chemical Society; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society, Nichols Medal award; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Manufacturers' Catalogs

PITTSBURGH IRON & STEEL FOUNDRIES CO., Pittsburgh, Pa., is distributing an attractive booklet on "Adamite in the World's Work," which illustrates and describes the performance of Adamite under severe operating conditions.

THE NORTON CO., Worcester, Mass., calls attention to a catalog on "Balancing Equipment for Grinding Wheels." Illustrations and descriptive matter are given, together with prices.

WALLACE & TIERNAN CO., INC., New York City, announces Technical Publication 23 on "Modern Bleaching Methods," which are based on the use of liquid chlorine with control equipment.

THE HARDINGE CO., New York City, calls attention to Catalog 8, on the Hardinge conical mill, and Grinding Data No. 4 and No. 5.

Ignorance in High Places

IT CAN be stated almost with certainty that legislation to protect our dye industry will not be enacted at this session of Congress. Responsibility for the delay, however, can with no uncertainty be laid to the opposition of Senators THOMAS of Colorado and MOSES of New Hampshire. The former in particular is known to have a constitutional antipathy for tariff protection, while the latter is said to oppose the Longworth bill in the interest of certain textile manufacturers. Whatever may be their reasons, their power to obstruct legislation is so thoroughly recognized in the Senate that the committee having the matter in charge does not feel warranted in bringing it up.

Seldom do we realize all the forces at work in our legislative halls, nor can we always delve deeply enough into these forces to discover the animus behind them. Sometimes it is partisan politics, sometimes personal interest, sometimes prejudice, and sometimes plain ignorance of the subject. The last is not only incomprehensible but quite unjustifiable in a day when knowledge and information are thoroughly organized and readily available. Nevertheless we find a curious instance in Senator THOMAS' opposition to protection of the American dye industry. In response to our efforts to convert him to the necessity of legislation on this matter he assured us first of his thorough knowledge of the subject and then asked if we were not aware of the fact that "the small volume of German dyes now in course of production is dependent very largely upon intermediates supplied from the United States." This fallacy being thoroughly fixed in the Senator's mind, he sees no reason why, if we "are so frightened over the prospect of drastic German competition or Germany's speedy rehabilitation as a war power," we cannot "easily limit her production . . . by cutting off this supply." The Senator expresses the hope that he may "live until that policy is adopted." In the meantime, however, he stands stanchly against protection of the dye industry because it is a sinister piece of legislation, the ultimate purpose of which is to create a huge combination of chemical activities in the United States. With full faith that the desired protection will be consummated by the next Congress, the Senator bravely avers that "it will never be so long as I have strength to prevent it." The Senator retires on March 4. In the meantime it is to be hoped that if the next Congress declares peace by legislation, it will simultaneously extend the powers of the War Trade Board Section of the State Department so that dye importation can still be controlled by license until appropriate legislation is passed.

Participation of Technical Men in Public Affairs

WRITING at the close of his term of office on the subject "This Country of Ours," President BENJAMIN HARRISON gave a bit of advice too often ignored by professional men. He said:

We have not realized in government, any more than in mechanics, inherent and perpetual motion. It is not enough to construct and start. Watchfulness, administration and love are needed to keep the best planned government on its projected lines. Men, rather more than machines, need watching.

There has been no time in the history of this country when more intimate attention to Government affairs was justified than at present. The chemist and the engineer, among others, have their responsibility clearly before them in these circumstances. Just now there are before Congress many important matters of legislation in which these technical professional groups are intensely interested. However, it is not enough to be simply interested in them; positive constructive action is required.

The recent experience of the chemical and engineering professions should justify all of us in venturing again into these legislative matters. Undoubtedly the effort made in the case of Patent Office legislation was the effective means for securing the favorable action on Patent Office salaries. The conferees from the House of Representatives and the Senate met with two salary scales before them. One was a distinct improvement over the present provision for the technical staff of the Patent Office, but even at that rather inadequate. The second provision cut the present limited staff in numbers and provided negligibly small increases for any grades in the staff. Under ordinary circumstances the result of conference on these two salary scales would have been a compromise; and, with the plea for economy sounding in the ears of all members of Congress, it is probable that the lower scale would have been adopted in most particulars. However, the technical men of the country, representing science and industry, demanded attention and as a result the members of both houses were convinced and have reported favorably upon the higher salary scale throughout.

In matters of dye legislation, chemical glassware importation (duty-free or otherwise), reorganization of the technical services of the Government, emergency tariff legislation, tariff revision, nitrogen legislation and other matters of this sort we find political factors which are beyond the experience of most technical men. With respect to these political factors we shall doubtless have to permit the professional politician to orate and finally to decide. There are, however, in each of these, and in numberless others, matters of technical

fact or of distinctly technical concern. With respect to these our professional engineers and chemists should be heard, and if they will but exercise "watchfulness, administration and love" they can and will be listened to attentively. The result will be a most satisfying participation in national affairs not only for the gratification of personal or professional desires but also for the general public welfare.

Chemical Warfare Service

An Investment for Economy

CHEMICAL warfare is the most effective, the most economical and the most thoroughly humanitarian arm of modern military service. It may seem anomalous to credit maximum effectiveness and humanitarianism to the same weapon, but it is a wholly justifiable anomaly.

Without effective defensive equipment for use in gassed areas, other arms of the military service are helpless. Within the range of even the "Big Bertha" troops cannot operate with impunity unless provided with defensive equipment adequate to cope with the most lethal gas which the enemy may choose to use. To send troops into the field without such equipment is worse than foolhardy. Yet that is substantially what the United States is proposing to do when it says to the Chemical Warfare Service that it may not expend each year a sufficient sum to develop, manufacture and replace from time to time with the most modern forms a supply of gas masks sufficient to equip perhaps three-quarters of a million troops within a period of thirty days. To send troops into the field with even the mask which was issued during the last months of the late war would be to place them in a defenseless position before any nation well equipped with the more modern types of gas shell. Yet that is precisely the condition which today is being authorized.

The Chemical Warfare Service has asked for a two-year period a sum approximately equal to $2\frac{1}{2}$ per cent of the total estimated Army appropriation. The War Department itself cut these requests nearly in half, and Congress seems inclined to even greater "economy." It is worth while, however, to determine whether this is real saving or simply a penny-wise policy.

It is well recognized that in future military operations against a well-equipped enemy a very large percentage of hospital cases are certain to be gas casualties. Every such casualty on the field of battle represents a tremendous cost in money, a material reduction in effective fighting strength and a large increase in the medical and hospital personnel and facilities. It is a well-known saying among military men that every wounded man requires two well men to care for him. And this is no exaggeration. Every ineffective mask is, therefore, potentially responsible for three persons rendered *hors de combat*.

The effectiveness of gas in modern warfare need not be emphasized. It is worth while, however, to recall again the fact that there is a much higher percentage recovery from gassing than from any other type of casualty. Thus one can well defend the claim that it is the most humanitarian of all means of attack upon combatants.

The chemical industries should appreciate the important points which can be made in support of chemical warfare. This type of warfare is really available only to a civilized nation of high industrial intelli-

gence. The industries of any nation developing chemical warfare to a full state of effectiveness will find simultaneous advantage to industry through the incidental organic chemical research. Indeed this alone probably would justify the expenditure. But more than this, industry can rest assured that if the nation is thoroughly prepared in this respect no other country has an opportunity effectively to attack us with hostile motive. Industry is thus both directly benefited and indirectly protected, and may well ask why the Chemical Warfare Service should not be provided with at least 2 per cent of the estimated Army expenditure, which is the very modest request the Service is making.

The Right Way To Do It

THE Committee on the Chemistry of Colloids of the Division of Chemistry of the National Research Council has issued a list of about 200 research problems prepared by Prof. WILDER D. BANCROFT, of which forty-five were published in the January number of the *Journal of Industrial and Engineering Chemistry* of the American Chemical Society, and forty-eight more in the February number of the same magazine. The list was issued last November, and it is hoped that the serial publication will be completed in April or May.

The work was undertaken to stimulate research, and the method has proved to have great merit. Of course it would be hard to find the equal of Prof. BANCROFT in the exposition of problems, but it goes without saying that these may serve as a pattern for others. No sooner had the first forty-five been published than letters began to pour in to the chairman of the committee, Prof. HARRY N. HOLMES, at Oberlin College, Oberlin, Ohio. For instance, an industrial chemist wanted to "team" with a university man better versed in theory than he, in regard to a problem in the chemistry of paints. Some men are asking for specific problems that they fancy. A prominent manufacturing company asks, in regard to one of the problems, to be put in touch at once with any good chemist who has selected it for his own research. It says it has some helpful information that it will put at his disposal. Here is the very thing that academic men accuse industrial concerns of not doing. They ask them to hand out results of their research, and lo and behold, it is done!

"Why," asked a chemist of Dr. HOLMES, "don't men in other fields of chemistry do the same thing: put out lists of stimulating research problems?" Well, why don't they? We've always been in favor of such a procedure, and in an editorial on "Metallurgical Mysteries" in a late number we intimated a number of such problems in the metallurgical field.

We congratulate the National Research Council on the sanity of the method of the Committee on Colloids and on the subtle intelligence with which the committee transacts its business. The open publication of problems reaches the man who wants to do the job, who has a leaning for it. It touches the person in whom the fires of enthusiasm are already burning. Instead of being assigned to a chemist, it is chosen by him; chosen because of his faith in his own ability to do this very thing. That is sound psychology.

Suppose instead of this direct, sincere work, the committee were to sit in high conclave and determine who is best fitted for each problem and then to allot them accordingly? Even if the committee sat on the top

floor of the Bankers' Trust Building, surrounded with Gothic tapestries, and rested in chairs specially imported from the Musée de Cluny, and smoked two-dollar cigars, it would still lack the pentecostal light to lead it unto wisdom. As likely as not its members would forget the one man in all the world who is best fitted to undertake it, who is, very possibly, making urine analyses for the country doctor to help out his salary as professor of chemistry at some Deepwater Baptist College in a town they've hardly heard of. But that one man does know, and as soon as he reads the call he answers it.

To our mind the Committee on Colloids is on the right track. Or, to mix our metaphors, we might also express the opinion that it is leading the band.

The Function of Educational Institutions in Research

SEVERAL weeks ago we attempted a delineation of two types of research, scientific and industrial, and suggested what seemed to us a logical allotment of those types to agencies best suited to conduct them. Briefly, the conclusion was reached that scientific research is best fostered in the laboratories of universities and government bureaus, while industrial research had best be left to commercial laboratories and consultants. The line is not drawn hard and fast, because it is recognized that industry may see fit to conduct scientific research of the highest order and that occasionally university and college laboratories may properly be devoted to the solution of industrial problems. The general distinction, however, we believe to be sound and in the best interests of all concerned.

An organization like the Mellon Institute is outside the scope of our criticism because it stands practically by itself and it is doubtful if commercial laboratories would fill the same need in the same way. Probably the success of the Institute has suggested the adoption of industrial fellowships at other schools, but it is not likely the same success will be attained elsewhere. The Mellon Institute had its inception in the mind of a far-seeing leader, and its realization was dependent upon financial support of such magnitude as is unlikely to be readily obtained.

The relation of universities and industrial research may be further discussed in view of the recent tendency on the part of some of our institutions of learning to establish industrial fellowships and engage in research and consultation. This attempt to combine two entirely different types of work in the same institution, and often under the same direction, must inevitably lead to an *impasse*. The primary function of the university is the education of its students. Presumably this education consists in the inculcation of broad elements of culture and the exposition of fundamental principles. The purpose and methods are quite distinct from those of industrial research having as its ultimate goal the discovery or improvement of a process or product. We doubt if the two can be prosecuted successfully side by side. One is likely to be subordinated to the other, and suffer in consequence. If the attempted service to industry is to be successful the institution must develop into a consulting organization to the detriment of its teaching function, while if the latter be exercised in the highest degree any attempt at industrial research is likely to prove abortive. If instruction suffers the result will be poorly equipped graduates whose field of en-

deavor has been narrowed by the almost certain prospect of competition with their own alma mater.

The whole question of competition between universities and their alumni looms up in this connection. It is argued that when universities enter into competition against established consultants they can usually underbid the latter by the offer of free laboratory service and the assistance of industrial fellows whose salaries are modest, but probably commensurate with their abilities. The result is unfair competition which affects not only the private consultant, who may be an alumnus of the institution, but also the industrial fellow who may be working on a problem beyond his capability, the instructor who divides his time between theoretical instruction and supervision of industrial research, the student who possibly suffers from this division of effort, and finally the company or organization supporting the research, due to possible dissatisfaction with the results of poorly planned or ill-advised investigation. The last is greatly to be deplored because it is likely to deter the other companies from undertaking industrial research and thus retard the progress of industry. In general it seems that the whole matter of industrial fellowships in universities would profit from a searching examination as to purpose, influence on instruction and value of commercial results. We believe it will be found that the search for the truth and the search for the dollar are different occupations and that their paths are not the same.

But if we do not regard industrial research as a legitimate activity for universities we are none the less confirmed in our opinion that there is a vast number of scientific research problems which they should undertake and which ultimately would inure to the benefit of industry. These relate to the fundamental data, properties, constants, etc., which are so badly needed by those who apply science in our technological industries. They are of the type discussed in our last Chemical Exposition number by Prof. RICHARDS, and subsequently by DONALD M. LIDDELL. It is just the sort of research which should make less arduous and difficult the work of the National Research Council in gathering data for American tables of chemical and physical constants. In fact there is enough scientific research to be done to keep a far greater number of men busy than are now engaged in it, and the place for it is in the atmosphere and surroundings of the university laboratory.

Another type of research which is quite within the scope of the university is of a semi-public character which is not likely to be undertaken by individuals or companies but from which they and the general public will profit. A typical example is the work undertaken by Dr. WITHROW at the University of Ohio in the study of the nuisance resulting from fumes from chemical manufacturing plants. Such an investigation will serve the state, the immediate community and the industry. Problems of this kind relating to public health or welfare undoubtedly exist in many communities and can be undertaken by universities, particularly if supported by the state. In general we feel that in deciding whether or not a certain line of research is legitimately within the field of the university a safe criterion will be the existence or non-existence of other suitable agencies, corporate or individual. With this in mind universities will find little excuse for excursions into industrial research, just as they will find little competition but much approval for their efforts in scientific research.

Readers' Views and Comments

Sulphur Dioxide May Have Therapeutic Value

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your Dec. 15 number is an article "Chlorine May Have Therapeutic Value." Sulphur dioxide gas may have a similar property. During the influenza epidemic of 1918, the working force of the British Acetones Co. at Toronto, Ont., was reduced nearly 30 per cent by cases of influenza, but in the sulphuric acid department not one of the eight men employed there suffered from it.

Duty-Free Apparatus for Colleges

To the Editor of Chemical & Metallurgical Engineering

SIR:—I note in your issue of Jan. 12 that Prof. J. W. Richards, in opposing the repeal of the duty-free importation privilege now possessed by our educational institutions, says: "Let's have a broader vision and have a further look ahead."

After reading Prof. Richards' arguments I was really surprised at his own very limited range of view in this respect. A look a little further into the future than Prof. Richards seems to have taken would disclose the fact that in the long run a properly protected industry in this country has, almost without exception, resulted in the development here of cheaper and better material than that previously imported from abroad. With this in mind, it seems clear that eventually if the manufacture of chemical supplies is properly protected here our technical students will have not only a better and cheaper supply but one near at hand.

This will result in much greater convenience in obtaining supplies and prevent what has occurred during the last six years—a complete cut-off of all supplies of this kind. Technical students then will never again be "hampered" in their training as they have been for the past six years and still are today. A duty on such supplies may cause annoyance for a short time, but ultimately they will undoubtedly be made better and cheaper here and the purchasing power of the educational funds will not be decreased but made greater in the long run. All of this will be conducive to increased efficiency in technical education.

It may be that for some time certain kinds of apparatus will not be made here, but eventually they will be and the amount of tariff paid by our educational institutions for these few items will certainly not constitute a heavy drain on their resources. They would also get a partial offset by cheaper freight rates. A tariff does not shut out foreign articles and hence would not prevent those who want to use foreign apparatus from doing so if they wish. An appeal to the patriotism and good judgment of the friends and alumni of any institution of higher learning that finds itself hampered by the increased cost of material due to a protective tariff on goods of American manufacture, levied for the purpose of developing American independence in such material, would certainly bring a response which would more than compensate for any temporary increased cost or embarrassment to the college.

I am sure when Prof. Richards gets a truly "broader vision and further look ahead" he and others of his view will not fail to see the advantages of developing our own supply close at hand and insuring against all future holdups of such materials by any foreign country.

Water Purification

To the Editor of Chemical & Metallurgical Engineering

SIR:—"A Comparison of Various Methods of Water Purification," by William Macklin Taylor, in your issue of Jan. 19, is of much interest and contains many suggestions which should be valuable when considering water softening.

As Mr. Taylor very properly states in concluding his article, ". . . it is apparent that each type of water purification has a fairly well-defined field in which it is unquestionably best." Speaking frankly from a precipitation water-softener standpoint, it seems to me that he claimed too much breadth of field for the admittedly discredited boiler compound method of softening.

The "soapy taste" which Mr. Taylor states is characteristic of lime-soda softened water is something which is foreign to the experience of the citizens of Columbus, Ohio; McKeesport, Pa.; Owensboro, Ky., and many other municipalities where softened water is used for domestic purposes. The complete satisfaction afforded by these and other lime-soda purified supplies scarcely checks with Mr. Taylor's sweeping statement in regard to the unfitness of lime-soda softened water for domestic use.

Small boiler installations where less than 500 gal. per hour of water is evaporated are not readily covered by the continuous type of lime-soda softener. For this service an intermittent or batch type of softener is particularly well adapted.

There is no doubt that certain substances can advantageously be added to water in boilers for the purpose of diminishing foaming and that certain others may be used to counteract electrolytic corrosion. This kind of treatment, however, has nothing to do with water softening. Where actual water softening is concerned—and the removal of calcium and magnesium salts from the water is required—the elimination of these objectionable substances by precipitation methods is universally conceded to be the best.

Practically every boiler plant engineer and certainly all steam railroad water service engineers have tried the boiler compound method. Of course they have used the most effective chemicals known as well as the "worthless components." As a last resort in preparing water for boiler feeding they turn to precipitation methods, as is witnessed by the increasing numbers of these plants being installed. The net result is that some railroads are already completely equipped and additional softeners are being installed elsewhere as rapidly as funds become available.

The Cordage Fiber Industry of the Philippine Islands

Description of the Production of Manila Rope Fiber From the Abaca Plant—Opportunity for Industrial Advances — Agricultural and Botanical Notes—Yield, Methods of Manufacture and Products Obtained From Fiber

BY DR. ALVIN J. COX*

ABACÁ (Manila hemp), the most important and valuable fiber and export product of the Philippine Islands, is the foremost commercial cordage fiber in the world. High-grade machine-laid ropes made from it usually have a tensile strength of more than 15,000 lb. per sq.in. Statistics given for abacá for 1919 by the Director of Customs for the Philippine Islands show that it comprised about 40 per cent of the total value of the exports and amounted to 121,247,668 kg. (267,305,034 lb.), valued at \$26,851,825. The last report issued by the same bureau covering the first six months of 1920 gives 86,891,232 kg. (195,175,085 lb.) valued at \$21,972,175. It was still in the lead in value as an individual export product, though the recent increase in the production of coconuts, tobacco and sugar cane which are exported as copra and coconut oil, cigars and in other forms, centrifugal and raw sugar, respectively, have reduced the percentage. The purchaser is now protected in the abacá materials which he buys due to government supervision and grading.

GROWTH OF EXPORTS

Abacá was first exported to the United States from the Philippine Islands early in the last century and from that time on the use of the fiber has been very popular and has rapidly extended. The Philippine Bureau of Agriculture Bulletin 12, pages 9 and 10, says that the first authentic account of the use of abacá or banana fiber in the Philippines is that given by an Englishman, Dampier, who lived in the Island of Mindinao in 1686; that in 1820 a sample of abacá was brought to Salem, Mass., by John White, a Lieutenant in the Navy, and that from 1824 to 1827 the fiber began

to be used quite extensively in Salem and in Boston. The figures in the accompanying table indicate the increase in production and exportation since these became of importance:

EXPORTS OF ABACÁ FROM THE PHILIPPINE ISLANDS

Year	Kg.	Lb.	Value in Dollars U. S. Currency
1850	7,700,000	17,000,000	
1860	27,000,000	37,500,000	
1870	28,500,000	62,830,000	
1880	46,000,000	101,500,000	
1890	62,700,000	138,230,000	
1900	81,600,000	179,900,000	12,240,000
1910	170,788,629	348,219,990	17,404,922
1920	86,891,232*	195,175,085*	21,972,175*

* For the first six months.

SPECIES OF PLANTS

The name abacá is applied not only to the fiber but to the plant from which it is obtained. Abaca *Musa textilis* *née* closely resembles the common banana *Musa sapientum* in appearance and habits of growth, but may be easily distinguished from it by its narrower, more tapering, and darker colored leaves. Plantain *Musa paradisiaca* is also a closely related species. The common banana produces a fiber similar in appearance to that from abacá but lacking in tensile strength. The fruit of the abacá somewhat resembles that of the banana but is smaller, full of black seeds, inedible and of no economic value. Abacá fiber frequently is called Manila hemp and is generally known to the trade by that name. However, it is not hemp and this designation is misleading. Hemp is the fiber produced by the plant *Cannabis sativa*. The two are quite different. Abacá is a hard, light, strong, resilient, durable structural fiber as described below, whereas true hemp is a tough, fibrous layer between the wood and the bark known as bast fiber which is characteristic of certain

*Director, Bureau of Science, Government of the Philippine Islands, Manila, 1912-19.

families of plants. In the Philippines there are many bast fibers that have an extensive local use as a substitute for abacá and in some parts of the islands—for example, the Ilocano provinces—the making of rope from bast fibers has a considerable commercial importance. When much exposed to moisture some bast fiber ropes are superior in durability to abacá rope and in a few cases have a breaking length—i.e., the breaking load divided by its weight per unit length—closely approaching that of high-grade machine-laid abacá rope.

THE ABACÁ PLANT

The true stem of the abacá plant has a diameter of about 2 in. and is that part which bears the fruit. The flower bud remains at the root until the plant has attained about its full size and then pushes rapidly upward. The stalk or trunk is formed by this true stem and the thickened petioles of the leaves which form overlapping layers around it, and the plant grows to be from 15 to 35 ft. high and a foot or even more in diameter.

The abacá plant has a perennial root, and may be grown for many years without replanting. As the stems mature the root sends up numerous suckers which make the subsequent stalks, so that after a time the plants no longer remain in accurate rows. The time required for development varies with different varieties and in different localities. Generally cutting may be begun in about two years after the original planting, and after three years a plantation should be in full bearing. It is customary to cut a plantation about every four to eight months and from two to four stalks per plant can be harvested at a time. All stalks do not

mature at the same time. The stalk is ready for cutting between the time of appearance of the flower and the development of the fruit. If cut before or after this period an inferior quality of fiber will be obtained. When the plant is in flower the large violet-colored flower bracts fall to the ground and make it easy when passing through a field to select the plants that are ready to be cut.

The stalk is cut on a slant 2 or 3 in. above the ground with a sharp bolo or large knife. A horizontal cut is to be avoided, for then water will collect on the stump and cause it to rot and thus injure the root and the remaining shoots.

PREPARATION OF ABACÁ FIBER

The fiber comes from the petioles and the quality varies with the different layers. That from the outer layers is usually coarse and dark colored. After the leaves have been trimmed from a stalk the petioles are separated one from the other and split into strips, the fiber being obtained from the outer portion of these strips. The next step is to insert a small sharp piece of bamboo or bone into a strip of petiole and, after starting the separation of the fibrous portion, pull it off in ribbons as long as the strip. The remainder of the strip is discarded. When a quantity of these ribbons has been collected it is pulled under a knife to remove the fleshy material from the individual fibers. The knife is held horizontally, serves as a scraper, and when it is desired to insert or remove a ribbon of fiber it is lifted by a crude spring controlled by a foot treadle. Every ribbon is passed under the knife twice, the second time to strip the end that the operator grasped during the first pull. As the abacá stalk contains a large percentage of water and is very heavy and the stripping equipment is light and easily transported, the latter is usually moved from place to place and the fiber extracted near the spot where the stalk is felled. The cutting and stripping should be done on the same day, else the petioles deteriorate and yield a dark-colored and inferior fiber. After the fiber is stripped it is hung on a pole, generally bamboo, in the sun to dry. The more quickly it is dried the whiter and more lustrous the fiber.

Numerous attempts have been made to extract abacá fiber with machines and a number have been used with a measure of success, but the major portion of the abacá fiber produced in the Philippine Islands is hand-stripped. The cleaning of the fiber, which is controlled by the condition of the knife blade, the pressure with which it is pressed against the block and the drying are very important, for upon them depend the important qualities of both strength and color. A method of stripping must not break, tangle, discolor, waste or in any way injure the fiber.

When thoroughly dry the fiber is tied into bundles and brought together into central warehouses, where it is carefully sorted into the different commercial grades and baled for export. In the final baling a certain amount of oil is generally used on the fiber.

The best marine cordage, oil-drilling rope, binder twine, trawl line, etc., are made of abacá. Although the chief use of abacá is as a cordage fiber, the conclusion should not be drawn that it is not suitable for other purposes. Abacá is used either in its natural color or dyed in the manufacture of matting, hats, bags, baskets, trays, slippers, belts, lamp shades, cloth, lace, etc. Abacá cloth is a gauzy fabric known as sinaway and is

much used by Filipino women for camisas (waists). Sometimes cotton or silk is woven with the abacá to make exceptionally beautiful fabrics.

COMMERCIAL CENTERS

The exportation of knotted abacá is an important industry in Cavite, Batangas, the Bicol and certain other provinces. There are also factories in Manila for manufacturing the tied abacá fiber into braid of various widths. The braid as well as knotted abacá is exported to Europe and Japan for the manufacture of ladies' hats, which are made by sewing strands of braid together. Abacá hats are also manufactured in the Philippine Islands.

There are many different varieties of abacá, frequently a dozen or more in a single locality. The principal differences between them are in color and shape of stem, color and size of leaves, greater or less tendency to produce suckers, resistance to drought, and in development, strength, delicateness and quantity of fiber. It is desirable to secure an abacá plant which is hardy, grows rapidly and withstands drought, which has a long, thick and not too tapering stalk, and which produces fiber in abundant quantity, of good quality and easily extracted.¹

The abacá plant is peculiar in that it cannot be grown

¹From Philippine Bureau of Agriculture Bulletin 12, p. 11.

elsewhere than in the Philippine Islands. Experimental plantings have been made in Borneo, India, the West Indies and other parts of the world. In some instances the plants grew fairly well, but the fiber was inferior. Abacá requires a uniform warmth without excessive heat for its best development. A cold climate will retard not only its growth but the development of the fiber as well. Heavy winds have to be avoided, for they seriously injure the heavy, broad leaves. Only in the Philippine Islands has the fiber ever been successfully produced as an article of commerce. This fact undoubtedly has been of great benefit to the Philippine planter. However, the lack of competition has resulted in the continuance of antiquated methods of cultivation and fiber extraction. There are still many differences in agricultural practices in the various provinces. With keener competition the best methods used by any province would be extended to every other district possessing the same soil characteristics.

DEMAND EXCEEDS SUPPLY

Even in ordinary times the abacá supply is insufficient and is constantly exceeded by the demand. Since the outbreak of the World War there has been an unusual shortage of abacá fiber and naturally the use of other fibers has been extended. There also has been an inclination on the part of some to use cheaper fibers wherever possible in manufactured products and to market them as abacá. Frequently Philippine maguey and other structural fibers are cheaper than abacá and are used as diluents in abacá rope and similar materials. It is impossible accurately to differentiate microscopically between maguey and abacá, and the small abacá fibers are smaller than large maguey fibers. Color tests to distinguish between abacá and other fibers have been developed by the Bureau of Science. A satisfactory method of staining has been devised which gives distinctive colors, such as golden yellow for abacá and pink for maguey.

Abacá is not grown generally throughout all the Philippine Archipelago, though it is distributed throughout the greater part, and its commercial cultivation is restricted to certain favorable districts where there are deep, mellow, fertile, well-drained soils, freedom from winds, a high humidity and an abundant rainfall uniformly distributed throughout the year, where it attains its highest development. Such natural agencies as temperature, amount of light and sunshine, winds and the evaporation of the soil moisture, exposure, altitude, humidity, the amount and distribution of the rainfall and other climatic and physical conditions exert an influence either favorable or unfavorable and are of as great importance in the production and quality of abacá as the inherent characteristics of the soil itself.

CONDITIONS REQUIRED FOR GROWTH

The structure of all banana plants and their habits of growth are such that a large and constant supply of moisture is required. The humidity which regulates plant transpiration is only second in importance to rainfall. In districts having a long and definitely defined dry season the cultivation of abacá cannot be carried on successfully unless a ground water table at an even depth or a practically constant available water supply in the soil can be maintained by irrigation.

In a paper entitled "Philippine Soils and Some of the Factors Which Influence Them," I pointed out that not

only is a rainfall well distributed throughout the year a condition absolutely essential to the success of certain crops such as abacá, coconuts, tobacco and rubber, but this distribution also controls the prevalence of certain species of plants of the native vegetation. A map upon which was charted the provinces with 5 per cent or more of total cultivated area in abacá, coconuts and tobacco differentiated the Philippine Archipelago into the western region having a prolonged dry season and the eastern and southern having a rainfall well distributed throughout the year about as accurately as one in which these two different types were plotted immediately from meteorological records. Some variation is noted in the eastern part of the islands due to the topography of the regions, but there is sufficient rainfall during even the driest months so as not seriously to interfere with abacá or other stable crop dependent on continuous rainfall.

1,000 ACRES UNDER PRODUCTION

Abacá may be cultivated up to 3,000 or 4,000 ft. above sea level, but above this height the temperature is not favorable to its best development. The most favorable locations are along the eastern and southern coasts. The most important provinces, sub-provinces and islands in order of the importance of their production are as follows: Leyte, Albay, Sorsogon, Ambos Camarines, Samar, Davao, Misamis, Surigao, Oriental Negros, Cavite, Zamboanaga, Cebu, Laguna, Tayabas, Mindoro, Capiz, Agusan, Bohol, Romblon, Occidental Negros, Panay, Batangas, Antique, Lanao, Palawan and Cotabato. It is grown to some extent in other provinces of Luzon and on many of the smaller islands. The amount of land under cultivation for the growing of abacá has been estimated at about 1,000,000 acres. It is quite difficult to get an accurate estimate, because the plant often is grown on small and widely scattered areas in remote places.

LITTLE CULTIVATING REQUIRED

In the best plantations there are usually about four hundred to five hundred plants to the acre, but the exact number varies with the character of the soil and the variety of abacá grown. Frequently camotes (native sweet potatoes) are set out at the same time or other crops are planted which grow rapidly. This system is advantageous in that the growth of weeds is prevented and the loose soil is not washed away where the land is sloping. Where the soil and other conditions are favorable, abacá may very profitably be grown on the same ground with coconuts until the latter come into bearing. Under the present system little cultivating is done except to keep the land clear of grass and weeds. As the abacá matures it shades the ground and the grass and weeds are much less.

TYPICAL ANALYSIS OF SOIL

The use of commercial fertilizers has thus far not been extensively practiced. The abacá lands as a class are very fertile and probably will not have to be fertilized for a long time to come. An analysis of soil from one plantation in the Cotabato Valley taken for purposes of illustration is as follows:

Constituent	Per Cent
Moisture (H ₂ O).....	7.39
Loss on ignition.....	13.20
Nitrogen (N).....	0.276
Phosphoric anhydride (P ₂ O ₅).....	0.201
Lime (CaO).....	0.31
Potash (K ₂ O).....	0.27

^aPhilippine Journal of Science, Section A (1911), vol. 6, No. 4.

The enemies of abacá, such as insect pests and plant diseases, are very few and the total damage which the plants suffer from such causes is very little and in the aggregate entirely negligible.

YIELD OF FIBER

The yield of fiber varies greatly depending upon the variety grown, the soil, climatic conditions, efficiency of the method of extracting the fiber, etc., but usually from ½ to 1 lb. of fiber per stalk may be obtained. Under ordinary conditions the annual yield will average about one-half ton of dry fiber per acre. The figures given at the outset of this paper for the first six months of 1920 show the export product to have an average value in Manila of 11½c. per lb. Therefore at the present time the annual gross return from an acre of land planted to abacá may be estimated at \$115.

The probable cost of establishing an abacá plantation, including rental, clearing, cultivating, etc., and bringing to maturity, will be about \$60 per acre, and the annual cost of subsequent care may be placed at one-tenth of this amount. Stripping is sometimes done on a share basis, but in any event the cost of harvesting, stripping and marketing the product should not exceed \$50 per acre. Therefore the first full crop should eliminate the debit balance and in subsequent years the net return should be at least \$50 per acre per annum.

The utilization of waste products will still further increase the revenue. It is believed that by the present methods of extracting the abacá fiber at least 25 per cent of it is wasted. For several years the Bureau of Science has been investigating the suitability of various materials for the making of paper pulp. Paper pulp manufactured from abacá waste was strong and of superior quality. It should be possible to utilize all of the abacá waste commercially for the manufacture of paper and such utilization should be a great benefit not only to the planters but also to the paper manufacturers.

The cultivation of abacá in the Philippines unquestionably is a most profitable branch of tropical agriculture and the opportunities for its extension are very promising. Prices seem to be fairly assured for some time to come and the planter who selects good land and modern methods of cultivation, fiber extraction and management should produce superior fiber at a minimum cost and have a handsome income assured.

Present Condition of Graphite Production in Madagascar

The French Ministry of the Colonies has just furnished the office of the Commercial Attaché at Paris information on the present production of graphite in Madagascar.

It is stated business conditions were so unfavorable during 1920 that no new producing districts were opened, no new company for the exploitation of graphite formed, and operations at a number of the old deposits ceased. This is explained by the fact that adverse conditions have recently necessitated selling graphite at a loss. Resumption of operations at the old beds is dependent only upon more favorable conditions, and new deposits will doubtless be discovered as soon as there is some incentive to greater production.

Previous decline in business is shown by the following figures covering exportation in metric tons (metric ton = 2,204 lb.) of graphite from Madagascar: 1917, 27,838; 1918, 15,015; 1919, 4,056.

Nitrogen and Case-Hardening

BY HENRY FAY

THAT nitrogen plays a more important rôle in steel than is generally supposed is evidenced by the increasing number of articles appearing in the journals on this subject; that it plays an important rôle in case-hardening operations is shown in the work of Brophy and Leiter which appeared in the Sept. 22, 1920, number of this journal and from some work which has been in progress in this laboratory during the past several years. This work is not in a state of completion and it is the purpose of this note merely to mention a few of the more important results already obtained.

The writer has long had a suspicion that the case-hardening produced by cyanide was partly a nitrogenizing process, and this was confirmed qualitatively about four years ago. The methods of analysis for nitrogen were so crude that it was thought desirable first to investigate the methods that had already been used for this determination. Dr. Frederick Hurum has investigated the various methods and he has demonstrated that the method of Grabe and Petré, with modifications as to apparatus, is the most trustworthy. Very accurate results can be obtained by this method. Whether or not the method is capable of determining all of the nitrogen is still an open question which is now under investigation, but it is quite certain that it is capable of giving all of the nitride nitrogen.

As an example of the nitrogenizing process which takes place when a steel is heated in cyanide, I shall quote the following results from Dr. Hurum's thesis. A round bar of low-carbon steel was heated in a cyanide bath for ten minutes at 830 deg. C. and allowed to cool in the air. Successive layers $\frac{1}{800}$ inch in thickness were turned from this bar and analyzed for carbon and nitrogen, with the following results:

Thickness of concentric layers in succession from outside toward interior, in.....	1	2	3	4
	$\frac{1}{800}$	$\frac{1}{800}$	$\frac{1}{800}$	$\frac{1}{800}$
Carbon, per cent.....	0.16	0.30	0.06	0.15
Nitrogen, per cent.....	0.57	0.201	0.155	0.027

It will be seen that the outside layer contains 0.57 per cent of nitrogen, which is indeed surprising when it is considered that this sample was treated for only ten minutes. The nitrogen progressively diminishes toward the center of the bar, but apparently penetrates at a slightly greater rate than carbon.

C. B. Sawyer in another thesis has made an experiment along the same line designed to compare the observed increase in weight of thin sheet iron when heated in cyanide with the increase of weight as calculated from the results of an analysis for carbon and nitrogen. The original analysis of the sheet iron showed 0.05 per cent carbon and 0.005 per cent nitrogen. Four pieces of this sheet iron, about 5 g. each, were cleaned, dried and weighed, then heated in sodium cyanide at 830 deg. C. for two hours, quenched in water, then washed, dried and weighed. The average increase in weight was 2.42 per cent. The analysis of a mixed sample from the four pieces shows 1.63 per cent carbon and 0.726 per cent nitrogen. The percentage increase in weight accounted for by the carbon-nitrogen analysis amounts to 97.6 per cent. This result seems to show conclusively that the reaction is essentially a carbonizing and nitrogenizing process.

Other processes for case-hardening than the cyanide method are also capable of introducing nitrogen into steel. A low-carbon nickel steel was case-hardened by Dr. Hurum in one of the best commercial bone-charcoal mixtures and from this bar successive layers were turned off and analyzed for carbon and nitrogen with the following results:

Thickness of successive layers, in.	1 $\frac{1}{100}$	2 $\frac{1}{100}$	3 $\frac{1}{100}$	4 $\frac{1}{100}$	5 $\frac{1}{100}$
Carbon, per cent.	0.61	0.48	0.22	0.19	0.14
Nitrogen, per cent.	0.031	0.025	0.019	0.0106	0.0037

The source of the nitrogen in this case is undoubtedly the ammonia from the raw bone, but the nitrogen in the air may also be involved to some extent.

Another striking illustration of the nitrogenizing process is shown in some specimens treated by Dr. Shimer's cyanamide process. The results obtained are the following results:

Number	Time in Cyanamide Bath, Hours	Temperature, Deg. C.	Carbon, Per Cent	Nitrogen, Per Cent
0	Original		0.050	0.0049
1	2	650	0.440	0.505
2	2	750	1.082	0.579
3	2	800	0.835	0.187
4	1½	900	1.293	0.123

Several important facts are brought out by this experiment:

1. Diffusion of carbon takes place below A_{c1} —viz., at 650 deg.
2. Nitrogen combines with iron and also diffuses below A_{c1} .
3. The nitrogen content decreases with the rise of temperature, indicating that equilibrium is reached at some lower temperature.

In the experiment carried on at 800 deg. C. the carbon content and possibly also the nitrogen content is low due to the cyanamide bath becoming exhausted. Cyanamide has been replenished in the experiment at 900 deg. C. and the results at that temperature are accurate.

That the absorption of nitrogen in case-hardening operations is a general process seems to be fairly well established. Further evidence bearing on this point is shown by the fact that practically all successful case-hardening mediums are either highly nitrogenous, containing bone, leather, cyanides, ferrocyanides, etc., or are so designed as to be capable of absorbing atmospheric nitrogen. Such mediums as the latter always contain an alkali of some nature. Of course the methods involving the use of carbon monoxide or a hydrocarbon are exceptions to this statement.

In an article, "On the Conduct of Finely Divided Iron Toward Nitrogen," Remsen has shown that "when iron . . . and certain nitrogenous organic substances are heated together with metallic sodium in an atmosphere of nitrogen a cyanide is readily formed." Bucher has used this reaction, substituting sodium carbonate for metallic sodium, as the basis of his process for manufacturing sodium cyanide. This reaction is undoubtedly a general one whenever iron, an alkali and air, or nitrogen, are heated together. There is a formation of cyanide, and the cyanide in turn reacts with iron, forming carbide and nitride, which diffuse into the steel, the depth

of penetration being dependent upon temperature and time. It is a well-known fact that iron in contact with pure wood charcoal is capable of being case-hardened only weakly, but if an alkali is added to this mixture the process is much accelerated, due undoubtedly to the formation of cyanide.

Ammonia reacts very readily with iron, forming nitride. Dr. Hurum has shown that the nitride is capable of being held in solid solution and that it acts in this respect similarly to carbon, forming an austenite. By microscopic means he has been able to show that a round bar when treated with ammonia under pressure will show on its outer surface an austenitic structure after quenching. At a short depth the structure is martensitic and further in is found free the familiar iron nitride. After turning off the outer layer the chips have been found to be non-magnetic and to have a much lowered A_{r1} temperature. The nitrogen concentration of the austenitic layer has not been definitely determined, but work is now in progress to this end. The formation of this nitride-austenite offers a probable explanation of the ease and rapidity with which steels are case-hardened in cyanide.

In view of the fact that steel combines so readily and with so much nitrogen, case-hardening can no longer be considered as merely a carbonizing process but must also be considered as a nitrogenizing process. The question of course will be raised as to whether the introduction of nitrogen is harmful. To this it may be answered that the evidence all points to its being beneficial, adding to strength and hardness, up to certain limits. As in the case of carbon, so with nitrogen, when increased beyond certain amounts new effects are produced. When it is definitely learned just how much nitrogen may be held in solid solution new light will be thrown on this subject.

Massachusetts Institute of Technology,
Cambridge, Mass.

Prevention of Tarnishing of Polished Metals Under Heat-Treatment

In a process recently invented in Germany, for protecting polished metals which have to undergo annealing, from the tarnishing which occurs under ordinary treatment, a solution of boric oxide is used. The solution is only applied as a very thin film over the articles to be annealed, but it is claimed that it completely excludes atmospheric oxygen. The film melts at a temperature varying between 550 and 650 deg. C., according to its composition, and acts as a protection so long as it remains solid. Steel, for example, remains bright when heated to the melting point of the composition, and no coloration takes place when the steel is tempered. It is stated to be still more effective in the molten or semi-molten condition, as it then forms a perfectly gas-tight cover round the article, even when heated to the highest temperature used in practice. The coating is perfectly fireproof, does not evaporate and dissolves any oxidized matter on the surface of the heated metal. The coating can be applied either as a powder, sprinkled or dusted over the surface of the objects to be annealed, or as a liquid. It is soluble in water and methylated spirit, and the work to be annealed is simply dipped in the solution and allowed to dry. The coating peels off on cooling, or it may be dissolved in warm water.—*The Engineer*, Nov. 26, 1920.

Notes on Monel Metal

A Brief Statement of the Physical Properties of This Natural Alloy, and the Commercial Uses to Which It Has Been Adapted—Its Resistance to Corrosion and Its Strength at High Temperatures Are Perhaps the Most Useful Properties

By PAUL D. MERICA

Superintendent of Research, International Nickel Co.

THIS alloy was introduced by the International Nickel Co. about 1905 and named after its then president, Ambrose Monell. It is a natural alloy produced directly from Canadian bessemer matte by roasting and reducing with charcoal and has the following average composition: nickel, 67 per cent; copper, 28 per cent; other metals (iron, manganese, silicon), 5 per cent.

Several grades of this metal are produced for different purposes of which the following typical analyses are given:

	C	Mn	Fe	Si	S
Rolled Monel metal sheet..	0.11	0.15	1.76	0.18	0.026
Rolled Monel metal rods...	0.26	1.78	2.00	0.20	0.035
Monel metal wire.....	0.12	1.66	2.10	0.13	0.025
Monel metal castings.....	0.18	0.25	1.90	1.06	0.03

It will be noted that the wire is made with low-carbon content in order that it may be readily cold-drawn, whereas hot-rolled rods are produced with somewhat more carbon in order to increase the ease of hot-rolling.

The practice in producing castings and malleable ingots of this alloy follows very closely that in the

from 1,040 to 1,100 deg. C., using the same precautions as in the case of nickel against oxidation and absorption of sulphur during heating. Rods are produced by hot-rolling or forging; from these, bright, cold-drawn rods are also produced by close-annealing and cold-drawing. Wire is drawn from hot-rolled, close-annealed wire rod about $\frac{1}{4}$ to $\frac{3}{8}$ in. in diameter. Annealing of hot-rolled Monel metal preparatory to cold-rolling or drawing is carried out at about 900 deg. C., preferably in charcoal boxes to prevent scaling. Light scaling, however, may be removed by pickling with sulphuric acid and ferric sulphate as in the case of nickel, but it is a slow and rather unsatisfactory process.

Monel metal is on the market in the usual commercial forms, sheet, bars, wire and various special manufactured forms such as wire cloth, screens, nails, chain, bolts, nuts, golf club heads, and in the form also of castings.²

METALLOGRAPHY

The elements entering into the composition of Monel metal form a continuous series of solid solutions with each other, consequently the structure of the annealed

production of malleable nickel and nickel castings which has already been described.¹ After bringing to pitch in the furnace—i.e., adjusting the carbon and oxide content—it is deoxidized with manganese, or ferromanganese, and magnesium, the latter being used in the same proportions as for nickel, and poured into ingot molds or sand castings. Unless so deoxidized it is, generally speaking, not malleable and cannot be rolled or forged.

The ingots so produced may be rolled or forged at

or rolled metal is quite simple and similar to that of nickel, consisting of grains of solid solution with small particles of the oxides (?) of magnesium and manganese. This is illustrated in Fig. 1; the typical structure of cold-drawn rods is illustrated in Fig. 2. The structure of cast Monel metal is, however, quite different from that of cast nickel and is that characteristic of solid solutions—i.e., the cored or dendritic structure illustrated in Fig. 3. The darker portions are richer in copper than the light areas, due to the selec-

²Booklets by the Monel Metal Products Co. and the International Nickel Co. describe the properties and uses of this alloy.

tive method of solidification. This heterogeneity of concentration is relieved by annealing and by the processes incident to hot forging or rolling.

Monel metal may be etched with satisfactory results by the use of the 50 per cent nitric acid solution containing 25 per cent of glacial acetic acid. It is also attacked by ferric chloride solutions, and such solutions are also suitable for metallographic etching; a solution containing 1 g. FeCl₃ to 2 c.c. concentrated HCl diluted to 2 or 3 volumes with water is recommended.

Monel metal exhibits the same phenomenon as does nickel of intercrystalline brittleness produced by exposure at rolling temperature to the action of oxidizing or sulphurizing gases.³

USES AND APPLICATIONS

The principal properties of this metal which render it of commercial value are perhaps the following: Resistance to corrosion, the bright nickel finish which it takes and retains, its strength and hardness particularly at high temperatures, and its resistance to erosion by water and steam.

Monel metal resists excellently the action of ammonia, solutions of ammonium hydroxide, fused and dissolved caustic alkalis and carbonates, fatty and many other organic acids, sea water, solutions of neutral salts such as alum, sulphates, chlorides, etc., gasoline and mineral oils generally, phenol and cresols, photographic chemicals, urine, dry mercury, dyeing solutions, alcoholic and other beverages. It resists fairly well the action of sulphuric, weak phosphoric, hydrocyanic acids, hydrofluoric, acetic and citric acid, ferrous sulphate and dry chlorine. It is not resistant to the action of hydrochloric and nitric acids, molten lead and zinc, potassium cyanide fused or in solution, sulphurous acid, ferric chloride and chromic acid.

Monel metal sheet showed the following losses in weight upon exposure to the action of boiling acetic acid for eight hours:

	Mg.
Loss in wt. per sq.in. per hour in 10% acid.....	0.07
Loss in wt. per sq.in. per hour in 26% acid.....	0.08
Loss in wt. per sq.in. per hour in 56% acid.....	0.11
Loss in wt. per sq.in. per hour in 90% acid.....	0.12

It lost 0.078 mg. per sq.in. per day during eight months' exposure to cold glacial acetic acid.

Because of its relative incorrodibility it has been used to some extent for roofing materials. The roof of the Pennsylvania Terminal in New York City is covered with Monel metal sheet, selected because of its superiority over other roofing materials demonstrated during a ten-year test. It is also used for window screens for the same reasons.

Both rods and castings are used to a large extent in the manufacture of pumps, pump liners, rods, valves,

etc., for handling sea water, mine waters and acid and alkaline corrosive solutions generally. One of the principal applications of the metal is in the construction of tanks and crates for pickling steel; rods are used for this purpose and have apparently proved superior to any other material. In this connection the results of corrosion tests of Monel metal rod in pickling acid are of interest. Rods exposed for ninety days to the action of continually renewed 6 deg. Bé. (6 to 7 per cent) sulphuric acid at 74 deg. C. lost weight at the average rate of 0.0045 g. per sq.in. per day, corresponding to the removal of a layer 0.00003 in. thick per day; the removal of a 0.1-in. layer would therefore require about ten years. In fact Monel metal pickle-pins and pickle-rods have been removed from service after eight years and were found to show practically no evidence of corrosion. Their average life is perhaps three years. On account of its resistance to corrosion the metal is also used in the construction of mining machinery, mine screens, dyeing machinery and equipment and in the chemical and oil industries for miscellaneous parts exposed to severely corrosive conditions.

Monel metal takes and retains a finish almost identical with that of pure nickel and is for this reason much used for small fittings, trimmings and stampings, for golf-club heads and for table cutlery. This property in conjunction with its resistance to corrosion by substances used in preparation of foods and in washing have made it valuable for the construction of certain cooking utensils and for washing tanks, cream separator machinery, etc.

The resistance of the alloy to steam erosion and its strength at high temperatures, which seems to be higher than that of the steels or bronzes, have caused its extensive application in the production of steam pressure valves and steam turbine blading. For these purposes it is well suited by further reason of the fact that its thermal expansivity is approximately equal to that of steel, with which it is usually associated in such construction.

Marine propellers have been cast of Monel metal. In connection with its quite widespread use in naval construction it may be recalled that the steam yacht Sea-Call was covered with Monel sheathing, in this particular case unsuccessfully, for the reason that the galvanic action between it and the exposed steel parts of the hull caused accelerated corrosion of the latter.

Monel metal is remarkably resistant to oxidation even at high temperatures (750 deg. C.) and is used for electrical resistance and spark-plug wire and other parts exposed to high temperatures. Monel metal is made up into screens of various types, into filter cloth for corrosive liquids, and into screw machine products of all kinds.

The physical properties of this alloy are described by the International Nickel Co.² Its melting point is about

TABLE I. TENSILE PROPERTIES OF MONEL METAL.

Material	Average Tensile Properties			Average Range of Tensile Properties			Reduction of Area, per Cent
	Yield Point, Lb./Sq.In.	Tensile Strength, Lb./Sq.In.	Elongation in 2 In., per Cent	Yield Point, Lb./Sq.In.	Tensile Strength, Lb./Sq.In.	Elongation in 2 In., per Cent

Wire { Annealed.....					60 to 75,000		
Hard drawn.....					110 to 150,000		

³CHEM. & MET. ENG., vol. 24, p. 198.

1,360 deg. C., its density in the rolled condition, 8.97 (0.323 lb. per cu.in.). The mean coefficient of thermal expansion between 20 and 100 deg. C. is 0.000015.

Its electrical resistivity in the form of wire is 42.5 microhm per cm. (256 ohm-mil per foot), temperature coefficient of resistivity 0.0019 per degree C. The thermal conductivity of Monel metal is one-fifteenth that of copper, or about 0.25 $\frac{\text{watt-second}}{\text{cm.-second-deg. C.}}$. The optical reflec-

tivity of Monel metal is not markedly different from that of nickel; values are given in a previous article.⁴

Monel metal is slightly magnetic and its permeability varies markedly with composition and mechanical and heat-treatment. An annealed rod containing 66.1 per cent nickel, 28.8 per cent copper, 2.68 per cent iron, 1.91 per cent manganese, 0.22 per cent carbon and 0.29 per cent silicon gave the following values of magnetic induction:

Magnetizing Force-Gausses	Magnetic Induction-Gausses
1	413
2	699
4	989
10	1,203
20	1,244
50	1,282
75	1,300
100	1,317
150	1,346

With varying treatment, values of the magnetic induction for a magnetizing force of 50 gaussses may be obtained varying from 500 to 2,000.

The modulus of elasticity (Young's modulus) is 22 to 23,000,000 lb. per sq.in.

Hardness varies with the form and condition of the metal, as may be seen from the following table:

	Scleroscope Hardness, Universal Hammer	Brinell Hardness 10-mm. Ball 500 Kg. 3,000 Kg.
Hot-rolled rods.....	20 to 30	100 to 130 145 to 170
Cold-drawn rods.....		150 to 170 180 to 200
Cast Monel metal.....	20 to 25	90 to 100
Monel metal sheet.....		
Annealed Monel metal.....	15 to 20	80 to 100

The tensile properties of Monel metal also vary largely with the composition, conditions and size of the rod; values are given in Table I. The proportional limit of hot-rolled rods averages from 30,000 to 45,000 lb. per sq.in., that for castings from 15,000 to 25,000 lb. per sq.in.⁵

⁴CHEM. & MET. ENG., vol. 24, p. 75.
⁵Specifications are issued by the U. S. Navy Department for this alloy in its different forms and from which further information may be obtained of its tensile properties.

TABLE II. TENSILE PROPERTIES OF MONEL METAL AND 30 PER CENT NICKEL STEEL AT HIGHER TEMPERATURES

—Rolled Monel Metal—					—Rolled 30% Nickel Steel—			
Temperature in Deg. C.	Tensile Strength, Lb./Sq. In.	Elastic Limit, Lb./Sq. In.	Elongation, per Cent in 2 In.	Reduction in Area	Tensile Strength, Lb./Sq. In.	Elastic Limit, Lb./Sq. In.	Elongation, per Cent in 2 In.	Reduction in Area
21	104,900	78,350	31.3	61.7	94,498	39,850	51.2	59.8
149	97,400	58,500	29.7	57.8	97,000	37,100	64.1	65.0

510								
555	47,200	26,800	28.1	60.7	36,350	15,500	37.5	55.7

TABLE III. TORSIONAL PROPERTIES OF MONEL METAL AT HIGHER TEMPERATURES

Material	Temp-erature in Deg. C.	Tor-sional Strength	Elastic Limit	Twist	
$\frac{1}{2}$ -in. rolled Monel metal.....	21	94,610	45,510	12 turns	150°
	196	83,030	33,940	5 turns	0°
	317	72,290	31,300	5 turns	205°
	426	40,610	10,910	6 turns	240°
$1\frac{1}{8}$ -in. rolled Monel metal.....	19	91,990	37,780	11 turns	150°
	196	78,030	36,140	4 turns	320°
	...	54,210	19,800	4 turns	340°
	317	59,591	26,123	4 turns	90°
	426	38,600	10,680	7 turns	50°

The torsional properties of Monel metal hot-rolled rods have the following range of values:

Shearing stress at outermost fiber at proportional limit, 20,000 to 40,000 lb. per sq.in.; yield point, 50,000 to 80,000 lb. per sq.in.; maximum, 75,000 to 95,000 lb. per sq.in.

Direct shearing tests on hot-rolled Monel metal rods carried out in the engineering laboratory of Lehigh University gave the following average results:

Diameter of Test-Bar, In.	Single Shear Max. Stress, Lb./Sq.In.	Double Shear Max. Stress, Lb./Sq.In.
1	55 to 61,000	115 to 127,000
$\frac{3}{4}$	45 to 50,000	90 to 103,000

Compression tests of rods and castings give the following results:

	Rods, Lb./Sq.In.	Castings, Lb./Sq.In.
Proportional limit.....	25,000 to 50,000	15,000 to 25,000
Yield point.....	60,000 to 70,000	20,000 to 30,000

Very few tests have been made of the resistance of Monel metal to the action of alternating stresses, but the indications of a few tests are that the hot-rolled rods about 1 in. in diameter will withstand approximately 10,000,000 complete reversals of stress—i.e., from tension to compression—at 25,000 lb. per sq.in., maximum fiber stress, these tests having been made on a White-Souther machine.

The effect of temperature on the tensile and torsional properties of Monel metal has been studied by Bregowsky and Spring,⁶ whose results are given in Tables II and III.

Arnott⁷ gives the following values which are the average of eighteen tests:

Temp., Deg. C.	Tensile Strength, Lb./Sq.In.	Yield Point, Lb./Sq.In.	Elongation in 2 In., Per Cent	Reduction of Area, Per Cent
20	92,700	47,700	51	69
320	86,200	38,100	48	62
410	75,700	35,600	49.5	63
500	64,300	34,100	45	56
630	36,300	23,300	33	...
700	23,100	17,700	27	36
905	6,300	3,600	27	28

It is evident that Monel metal retains its strength to a remarkable extent at higher temperatures as compared with brasses, bronzes and steel.

Webster⁸ has studied the effect of cold-rolling on the tensile properties of Monel metal and has given the following values:

Material	Tensile Strength, Lb./Sq.In.	Elongation in 4 In.	Reduction of Area
Normalized Monel.....	79,000	26	35
Same after 20% reduction...	102,000	4	22
Same after 40% reduction...	118,000	3	18
Same after 60% reduction...	132,000	2	17

⁶Proc., Int'l Asso. Testing Materials, 1912, Sec. 1, Paper VII.
⁷J. Ind. Metal., vol. 23, p. 545 (1920).
⁸Proc., Int'l Asso. Testing Materials, vol. 7, p. 6 (1912).

A preceding discussion on the effect of impurities on the properties of nickel^o apply with almost equal force to Monel metal. Carbon, as in the case of nickel, hardens the metal and renders it easier to roll and forge hot, but more difficult to roll cold. The separation of graphite begins at a somewhat lower content of carbon than in the case of nickel, in the neighborhood of 0.35 per cent.

Although a long, tough chip is produced in the machining of this metal, it may readily be machined when proper conditions are observed. Tools are required of high-grade, high-speed steel and should be ground with large rake or lip and kept sharp. It may be machined either dry or with lubricant and a good average speed for general work is from 50 to 60 ft. per minute with a $\frac{1}{8}$ -in. cut and $\frac{1}{32}$ -in. feed.

Monel metal may be soldered and brazed in the same manner as iron or steel. It may be acetylene-welded. The welded joint will, however, not be as strong as the original metal and will have little ductility. Ordinary Monel metal wire rod may be used as the welding rod. Acetylene welding of this metal as well as of nickel should be executed with a nearly neutral flame, as the metal is highly sensitive at these temperatures to the presence of oxygen. Welded Monel metal and nickel tubes are being manufactured by the oxy-acetylene process.

British Lubrication-Research Report

The British Department of Scientific and Industrial Research has just made public the final report of the lubricants and lubrication inquiry committee appointed by the advisory council in 1917 "to prepare a memorandum on the field for research, containing an analysis of the problems involved, together with a suggested scheme of research which would be likely to lead to valuable results." The work accomplished may be thus stated in brief:

(a) The compilation of a bibliography of the chemical, physical and engineering aspects of lubricants and lubrication.

(b) The compilation of abstracts of important papers contained in the bibliography, especially in relation to chemical aspects of the subject.

(c) Research work on certain fundamental problems on which knowledge was lacking.

(d) Tests and reports on certain matters brought to the committee's notice by the department.

(e) The preparation of bulletins on cutting lubricants and on solid lubricants.

The work instituted by the committee at the National Physical Laboratory and elsewhere covered.

Tests with Lanchester worm gear.

Effects of pressure on viscosity.

Determination of the physical constants of oily and non-oily liquids.

Further apparatus for testing the effect of pressure on viscosity in an actual bearing.

Deeley's oil-testing apparatus.

Cup-and-ball viscosity tester.

Test of lubricating oils for aircraft purposes.

Experiments on cavitation on oil films.

Experiments on the addition of gelatine to oil emulsions to prevent separation.

Tests on a sample of compounding medium for lubricating oils.

Trials of "Oildag" in aëro engines.

Determination of the frictional coefficient of a shaft bearing, using oil with and without "Oildag."

Proprietary article called "Tonicol."

As to the future the committee recommends that research be carried on under these headings:

1. To isolate and determine the nature of the hydrocarbons in mineral lubricating oils which especially promote the properties of viscosity and "oiliness."

2. To determining the classes of hydrocarbons desirable in lubricants required to work under high pressure and high temperatures, particularly as regards their relative stability under the conditions obtaining in internal combustion engines, steam engines and air compressors.

3. To study the causes and means of preventing the formation of carbonaceous deposits from lubricating oils under the conditions named in (2), with special reference to the nature of the hydrocarbons, sulphur compounds, and resinous constituents of such oils.

4. To study the causes of emulsification in circulating oiling and in splash systems, with special reference to (a) the influence of the sulphur compounds in mineral oils, and (b) the characteristics of oils with non-emulsifying properties.

5. To study the causes of oxidation in circulation oiling systems, also the causes of formation of oxidation products in bearings and on bright metal surfaces.

6. To determine the direction in which the processes of manufacture can be modified so as to lead to the production of lubricating oils of improved types.

SYNTHETIC LUBRICANTS TO MEET SPECIAL REQUIREMENTS

7. To discover new methods of analysis which will enable the chemist, when examining a lubricating oil in the laboratory, besides determining its viscosity, specific gravity, flash point, etc., to determine the constituents of the oil and with the help of the knowledge gained under (1) to (5) to measure its ability to reduce friction and to meet the conditions of speed, load, temperature, and atmosphere in which it is required to work. Much of this information can be ascertained today only by the costly method of trial.

8. To elaborate further methods of producing lubricants synthetically in order to meet special requirements. Dicrosylcarbonate, for example, has been used as a lubricant. Reduced naphthenes, glycerides of naphthenic acids, and cinnamenes have been prepared and shown to have lubricating value. It might be found possible to produce lubricants whose rate of change of viscosity is less and whose freezing point is lower than is the case with existing lubricants.

9. To prepare in a pure state the esters met with in animal and vegetable lubricating oils and determine their relative lubricating values.

ADDITION OF FREE FATTY ACIDS TO MINERAL OILS

10. To investigate the claim that the free fatty acids present in commercial fixed oils are the active constituents which enable these oils to improve the lubricating value of mineral oils, and to investigate further whether the addition of such acids to mineral oils may, in certain circumstances, improve their lubricating value.

11. To investigate the colloidal nature of lubricating oils and its bearing upon lubricating problems.

12. To study the effect of ultra-violet light, sunlight and ozone upon lubricating oils.

13. To investigate the phenomena of dissimilar surfaces (oil and metal) in contact, especially in relation to the property of oiliness.

Conservation of Heat in Power and Heating Systems*

Discussion of 85 Per Cent Magnesia Insulation, Showing Low Depreciation Rate Under Wetting and Drying and High-Temperature Conditions—Chart for Determining the Economical Amount of Insulation—Amounts of Coal, Heat and Money Saved by Insulation

BY EDWARD R. WEIDLEIN†

THERE are two distinct methods of conducting scientific research for industry. Each of them has its advantages and, generally speaking, both are followed in investigational practice. The first is the more obvious. It consists in taking problems which are quite familiar and attacking them with the powerful weapon which science has placed in the hands of its trained workers. This method is capable of very wide application and has afforded most valuable results.

The second method is not nearly so obviously useful, but the history of scientific discovery reveals that it is extremely powerful. It consists in beginning not with a definite problem, but with the systematic application of the different branches of science to the study of a material of economic value, for the purpose of gaining as complete knowledge as possible of the nature and properties of the material. At first sight this procedure may appear to business men to be very indirect, but the experience of some of our most enterprising industrialists and associations of manufacturers shows that in the long run it is more profitable than the obvious and direct method.

If it is conceded that the indirect method of approach is often the better, it must be borne in mind that it is usually the slower. This has been the case in the Mellon Institute's elaborate study of the characteristics of "85 per cent magnesia" as a non-heat-conducting covering for power and heating systems.

The industrial applications of insulating materials may be divided into three main classes—viz.: (1) Boiler plants, steam pipes, and heated surfaces of all descriptions; (2) refrigeration plants and cold storage; and (3) furnace settings. This paper will be confined to a consideration of the conditions encountered in the first-mentioned class, for all the data which have been obtained so far relate to the conservation of heat losses from pipes and boilers.¹

FUEL ECONOMY IMPERATIVE

Heat insulation in all its varied aspects has a great future, since it is of recognized value in reducing working expenses, and specifically it is of very material aid

in effecting fuel economy. It is recognized generally that the losses from bare pipes and boilers are considerable, but the real magnitude of these losses is little appreciated. The fact that the loss from 1,000 sq.ft. of exposed surface at 100 lb. per sq.in. steam pressure represents over 300 tons of coal annually is a sufficient justification for the serious consideration of the subject.

The need for economy is becoming more imperative since the prospect for low-priced fuel in the immediate future does not seem to be very encouraging. Accordingly, there have been introduced improved methods of combustion, resulting in the operation of boilers at higher steam pressures and a general advance in boiler-room efficiency. However, the improved steam production is nullified to a large extent unless improvements are also made in the steam conveyances. Higher boiler pressures necessarily imply higher steam temperatures, and higher temperatures inevitably call for reconsideration of the whole question of insulation. The proper amount of non-heat-conducting material which should be applied to any heated surface will be that at which the cost of an increment of the covering will just balance the savings which will be accomplished by the increment.

GOOD INSULATING MATERIALS

A good heat-insulating material should have low heat conductivity; low specific heat, it being necessary that as little heat as possible should be absorbed by it; low specific gravity, in order to avoid the addition of undue weight and the introduction of undesirable strains in the piping systems; and sufficient mechanical strength to withstand vibration and accidental knocks. Moreover, it should be capable of withstanding the action of water and, preferably, also acids; it should be one which does not crack with alternate heating and cooling and with alternate wetting and drying; it should not disintegrate or decompose at the temperature to which it must be exposed; it must have no corrosive action on the surface to which it is applied; and it must be non-flammable.

Air is a poor conductor of heat. The transmission of heat through air is effected not in a considerable degree by conduction, as in the case of metals, but partly by radiation and largely by convection or by the currents set up by the difference in specific gravity of hot and cold air. This explains, therefore, why a good non-conductor of heat is generally found to be a porous material, or one which has entrapped pockets of air throughout its substance. For the highest insulating efficiency, it should have a uniformly honeycombed structure, and these pockets of air should be sufficiently small to prevent convection currents being set up in them.

The value of "85 per cent magnesia" as a non-heat-conducting material is increased greatly by the inter-

*Read before the American Institute of Chemical Engineers, New Orleans, Dec. 6, 1920.

†Associate Director of the Mellon Institute of Industrial Research, University of Pittsburgh, Pittsburgh, Pa.

¹The data presented in this report represent part of the results obtained during the course of an investigation conducted for the Magnesia Association of America by the Mellon Institute of Industrial Research. The object of the investigation is to determine the true facts regarding the value of "85 per cent magnesia" as a heat-insulating material, and therefore the data are confined to this particular covering, and no effort has been made or will be made to furnish comparisons with other heat-insulating materials.

The researches carried out at the Institute under the supervision of the author have been conducted by the following industrial Fellows: G. F. Gray (1917), Glen D. Bagley (1918), M. S. Mason (1919), T. S. Taylor (1920) and R. H. Heilman (1917-1920), the present incumbent.

The author wishes to express here his appreciation of the accomplishments of these Fellows and his gratefulness to P. Nicholls, of the Franklin Manufacturing Co., Franklin, Pa., for his constantly helpful co-operation during the progress of the investigations.

FIG. 1. FLOW SHEET SHOWING THE MANUFACTURE OF "85 PER CENT MAGNESIA"

lacing and felting together of the crystals to produce a block of magnesia containing 90 per cent of voids, which take the form of exceedingly small air pockets.

The name "85 per cent magnesia" denotes the fact that the coverings contain 85 per cent of basic magnesium carbonate, which is usually expressed by the following formula:

The remaining 15 per cent is asbestos, which is introduced as a binder to insure the requisite structural strength and durability. The flow sheet shown in Fig. 1 illustrates the method of manufacturing this product.

Pennsylvania dolomite rocks contain about 43 per cent of magnesium carbonate. The basic carbonate is separated in a pure form by a chemical process and is mixed with 10 to 15 per cent of asbestos fiber, after which the standard shapes and sizes are formed by a molding process. After the drying process, which requires five or six days, the rough-molded sections are planed to true dimensions. The heat insulation value is due largely to the mass of minute air cells formed by the interlocking walls of the crystals. This is also the reason for the extreme lightness of the product and for the ease with which it will absorb nearly three times its own weight of water. The Philip Carey Co., Cincinnati, Ohio; the Ehret Magnesia Manufacturing Co., Valley Forge, Pa.; the Franklin Manufacturing Co., Franklin, Pa., and the Keasbey & Mattison Co., Ambler, Pa., have supported this investigation through the Magnesia Association of America and they represent a total invested capital of \$16,500,000, which indicates the magnitude of this branch of chemical industry.

In a study of the conservation of heat losses, the first important fact to be considered is the actual value of the losses from bare surfaces. It is often considered that the loss from any bare surface is 3 B.t.u. per sq.ft. per hour per deg. F. temperature difference between the surface and the surrounding air. While this value is correct for some special cases, it is by no means generally so.

HEAT LOSSES FROM BARE AND COVERED PIPE

The full curves given in Fig. 2² show heat losses from bare pipes as predicted from Peclet's formula, and the dotted curve and points indicate the experimental results obtained by various investigators. The Peclet values agree closely with the experimental findings and can safely be used. They show that the constant may vary 50 per cent below 3 B.t.u. per sq.ft. per hour per deg. F. to values far above it. At 500 deg. temperature difference, which is often attained with superheated steam, the constant increases to double this value for the smallest size pipe. In some chemical plants steam is used at temperatures of 1,100 deg. F. The importance of using very thick insulation at these temperatures is easily judged from the rate at which the loss increases at 500 deg. F.

The next important point in a consideration of the conservation of heat is the value of the loss after the pipes are insulated. The electrical apparatus used in securing the experimental data is designed to test the material under conditions corresponding to actual practice. Tests have been made on five different makes of magnesia coverings in 1-in., 2-in. and 3-in. thicknesses. The results of the tests are given in Fig. 3. The contrast between the losses from a bare pipe and the losses through the various thicknesses of coverings is very striking. The efficiency increases with the temperature,

²See Bagley, *Trans., Am. Soc. Mech. Eng.*, vol. 40 (1918), pp. 667-94. Bagley presents detailed information regarding methods of tests and results.

FIG. 2. HEAT LOSSES FROM BARE PIPE

for the loss from bare pipe increases much more rapidly in proportion than the loss from covered pipe.

DEPRECIATION RATE LOW

Pipe coverings may be subjected to wetting from leakage, floods, careless use of the hose, etc. Then, too, the necessity of removing and replacing the covering may arise. These questions, together with many others with regard to the permanency of the insulating qualities, rendered it necessary to conduct a careful investigation in this field, not only of new coverings but of coverings which had been in service for a number of years.

Tests were made to determine the effect of alternately wetting and drying coverings in relation to the change in heat conductivity, the change in mechanical structure and other physical chemical properties, and the possi-

FIG. 3. HEAT LOSSES THROUGH "85 PER CENT MAGNESIA" COVERINGS ON 3-IN. PIPE

bility of removing and reapplying coverings which had been wetted.

The following routine test was made:

1. Inspect, photograph, weigh, measure and apply the sections of pipe covering.
2. Heat the covering forty-eight hours at a pipe temperature slightly above 212 deg. F.
3. Measure the heat conductivity of the covering up to 400 deg. F. (temperature difference from pipe to air).
4. Immerse the covering in water for thirty minutes, then dry the covering on the pipe at a temperature difference not exceeding 400 deg. F. Wet the covering four times, drying it after each wetting. Conduct the fourth drying at pipe temperatures of 212 and 250 deg. F.
5. Measure the heat conductivity up to 400 deg. F. temperature difference from pipe to air.
6. Observe and record the physical effects of the test upon each covering.

The magnesia coverings were successfully removed after each drying, then weighed, soaked, weighed again and reapplied four times. Fig. 4 is a photograph taken

FIG. 4. CONDITION OF "85 PER CENT MAGNESIA" COVERING BEFORE (TOP) AND AFTER (BOTTOM) WETTING AND DRYING TESTS

of the covering before and after the wetting and drying tests. The heat conductivity is shown in Fig. 5 before and after wetting. The insulation value is increased, but in all cases the average shows the same conductivity before and after wetting and drying. The coverings were as strong after the test as before and could readily be reapplied, giving further evidence that they had not deteriorated; "85 per cent magnesia" has a crushing strength of about 100 lb. per cu.in., which is more than sufficient to withstand any of the ordinary strains or proper conditions under which it should be used.

Tests were made on several old magnesia coverings. Fig. 6 shows the conductivity of a 1-in. thick covering which had been in service for eight years at the Armour Glue Works in Chicago. The insulation value was slightly higher than the average of the new 1-in. coverings tested, showing that no deterioration in service had taken place. In the Niagara Power Station, in Buffalo, N. Y., "85 per cent magnesia" has been in service from sixteen to twenty years. A section and blocks were

FIG. 5. COMPARISON OF "85 PER CENT MAGNESIA" COVERING BEFORE AND AFTER WETTING AND DRYING TESTS

tested and found to have increased in insulation value approximately 3 per cent. Several sections were obtained which had been saturated with oil. Tests on these showed much lower insulation values than new coverings. The damage was permanent and showed that care should be taken to protect coverings from oil while in service. Figs. 7 and 8 illustrate the conditions to which coverings are sometimes subjected and the value of having a good permanent covering.

Upon inspecting various installations of insulated

steam pipes, it has frequently been noted that the pipe has suffered considerable deterioration. This rusting of the steam pipe has in many cases been explained as being due to the action of the particular covering on the pipe, and not simply to oxidation on account of the pipe and coverings being frequently wetted.

The results of tests conducted in order to determine the probable influence of various factors on the rusting of insulated steam pipes indicate that the pipe coverings, in general, especially if alkaline in composition, do not of themselves promote rusting on steam pipes when they become wet. In fact, they really act as a protecting coating, since the oxygen does not get into intimate contact with the surface of the pipe. However, an electric current flowing through the covering may either promote rusting of the pipe or it may retard corrosion, depending upon the direction in which it is flowing. When the current flows from the pipe to the outside of the covering, this causes the oxygen separated by electrolysis to be liberated at the pipe, thus promoting the

FIG. 6. COMPARISON BETWEEN OLD AND NEW COVERINGS

rusting of the pipe. The greater the current flowing the greater will be the rusting effect, so that if sufficient current were flowing a covered pipe might rust as much as the uncovered. When the current flows from the outside of the covering to the pipe, hydrogen formed by electrolysis is liberated on the pipe, which tends to retard any rusting of the pipe. The action of the electric current would be the same on an uncovered pipe, and the quantity of rust formed no doubt would be in the same proportion as was found in the cases of the exposed and covered pipes.

As the tendency in industry is to use higher temperatures, tests have just recently been completed at a temperature of 800 deg. F. The pipe was maintained

FIG. 7. THIS PIPE, COVERED WITH "85 PER CENT MAGNESIA," WAS SUBMERGED FOR THREE WEEKS BY FLOOD WATER WITHOUT DAMAGE

FIG. 8. EXPANSION JOINT IN 750-FT. 22-IN. PIPE LINE CARRYING STEAM AT 150 LB. "85 PER CENT MAGNESIA" COVERING ON THIS LINE SAVES 1,300 TONS OF COAL ANNUALLY

at a temperature of 800 deg. F. for a period of two months. The covering showed the average conductivity value, and after the test was not only successfully removed from the pipe but was in such a condition that it could have been successfully reapplied.

This agrees with the results obtained under actual working conditions in the plant of the Buffalo General Electric Co., Buffalo, N. Y. This company has in service 10-in., 6-in. and 3-in. steam lines which carry steam 75 per cent of the time at a temperature from 650 to 700 deg. F. with a peak temperature of 800 deg. F. The pipes have been covered with "85 per cent magnesia" for four years, and Fig. 9 shows a section of the covering removed from the 6-in. vertical steam line in perfect condition.

THE ECONOMICAL AMOUNT OF INSULATION

A careful study of the technical and theoretical sides of any problem is essential in order to determine the economic value of the process or product, and so with

FIG. 9. SECTION IN USE FOUR YEARS AT TEMPERATURES FROM 650 TO 800 DEG. F.

"85 per cent magnesia" covering the result desired is the maximum net saving of money for any given condition. If the covering cost were nothing, the proper thickness would be limited only by the requirements of space available, for each increased thickness would result in some slight increased saving in heat. In a prac-

FIG. 10. THICKNESS OF COVERING FOR MAXIMUM NET SAVING WITH STEAM AT 20c., 40c., 60c. AND 80c. PER MILLION B.T.U.

tical case where the covering has a definite cost, a point is reached where the increased cost of the covering will be greater than the additional saving in heat effected. It is this point in which the user of coverings is most interested, for it defines the maximum net saving to be accomplished.

One important factor to take into consideration is the fact that prices of coverings vary with the thickness. For flat surfaces the price is directly proportional to the thickness, starting at 30c. per sq.ft. for coverings 1 in. thick. The difficulties encountered in the manufacture of molded coverings for pipes result in an increased cost per sq.ft. for a 1-in. thickness, and the cost increases much more rapidly with the thickness than in the case of flat surfaces. More material is also required in molded coverings per sq.ft. of pipe surface than in the same thickness in flat blocks on account of the curvature of the surface.

The cost per sq.ft. of surface covered can be determined for any thickness desired. From this cost the annual fixed charges due to the covering can be calculated. After considerable investigation, it has been determined that 20 per cent of the list price of the covering would be a fair allowance for the cost of application, and 13 per cent of the total cost as the annual charges (6 per cent interest, 5 per cent depreciation and 2 per cent insurance and miscellaneous). This fixed charge has been calculated for seven different sizes of pipes and five different thicknesses, based on the manufacturers' list costs of coverings.

The other cost to be charged to the operating expenses of the covering is the value of the heat losses through the different thicknesses of coverings. The previous work done on measuring the loss through a large number of samples of magnesia furnished the necessary data for calculating the loss in heat units.

After the heat loss was determined, it was necessary to convert the loss into dollars and cents. The assumptions used in making this conversion were that 1 lb. of coal as burned will evaporate 7 lb. of water from and at 212 deg. F., and that each pound of steam contains 1,000 B.t.u. above the feed-water temperature. The value of the heat losses was calculated for seven sizes of pipes, five temperature differences between pipe and air, and four different costs of heat, both on the basis of a known cost per million B.t.u. and on a cost per ton of coal and the average conditions of steam generation given here. By making these calculations both ways, the results are applicable to plants where the steam costs are accurately known as well as to those where accurate records are not kept.

By combining the fixed costs and the heat losses per sq.ft. per year, the total operating expenses were obtained. Once these are known, it is simply a matter of selecting that thickness which gives the minimum annual operating expense to obtain the proper covering to use. It is evident that the thickness which gives the minimum operating expense also gives the maximum net saving, as the loss from bare pipe is a constant under given conditions and the net saving is the difference between the operating expense and the loss from bare pipe. The curves in Fig. 10 are for use in plants where heat costs, steam temperatures, etc., are accurately known. They are applicable to all heated surfaces, since they are based on the temperature of the surface and the value of the heat in dollars per million B.t.u.

AMOUNTS OF COAL, HEAT AND MONEY SAVED BY INSTALLATION

The savings accomplished by the use of the economic thickness of pipe covering is comparatively very great. The use of "85 per cent magnesia" of suitable thickness will result in a saving which will repay the original cost of the installation in less than a year in practically

TABLE I. MONTHLY SAVING, IN DOLLARS AND CENTS, BY THE USE OF "85 PER CENT MAGNESIA" PIPE COVERING

Standard thickness, per 100 lineal feet of steam-pipe							
Size of Pipe	5 Lb. Steam Pressure	10 Lb. Steam Pressure	50 Lb. Steam Pressure	100 Lb. Steam Pressure	150 Lb. Steam Pressure	200 Lb. Steam Pressure	200 Lb. Steam Pressure, 100° Superheat

every case, and under constant operation at high temperatures where great thicknesses are called for the saving will often pay for the installation in as short a time as two months.

Table I shows the actual cost saving per month with \$5 coal by the use of "85 per cent magnesia" pipe covering. Table II shows in greater detail the serious losses which are going on in many plants today—losses

which are wholly preventable but which amount in the aggregate to many tons of coal yearly.

BOILER TEST CHECK ON LOSSES

In order that the results of the laboratory test might be checked on a larger scale, several practical tests were made. The first and most important of these was a boiler test made at a mine in Bruceton, Pa. There were two boilers in the plant, of 80 and 60 hp., locomotive type. The total exposed surfaces on these boilers amounted to 675 sq.ft. The tests covered a period of

TABLE II. COAL SAVED BY "85 PER CENT MAGNESIA" COVERING 1-IN. THICK

Steam Pressure	Saturated 5 Lb.	Saturated 10 Lb.	Saturated 50 Lb.	Saturated 100 Lb.	Saturated 150 Lb.	Saturated 200 Lb.	200 Lb. Pressure with 100 Deg. Superheat

B.t.u. loss per hr., sq.ft. bare pipe	367	409	625	802	937	1,058	1,735
B.t.u. loss per hr., sq.ft. of pipe covered with "85 per cent magnesia" ..	69	76	105	126	142	153	210
B.t.u. saved per sq.ft. by covering pipe with "85 per cent magnesia" ..	298	333	510	676	795	905	1,525
Tons (2,240 lb.) coal saved per 10,000 sq.ft. per yr. of 8,760 hr. by pipe covered with "85 per cent magnesia"	1,190	1,330	2,080	2,700	3,180	3,620	5,650
Cars of coal saved year, as above, at 40 tons per car	30	36	52	68	80	90	140

twenty-four hours. Conditions of load, etc., were practically the same during both tests. During the first test, while the boilers were uncovered, 10,784 lb. of coal was burned to evaporate 58,000 lb. of water. In the second test, after the boilers had been covered with 2 in. of "85 per cent magnesia" blocks and plastic, 9,296 lb. of coal was burned to evaporate 59,500 lb. of water. The evaporation rate during the first test was 6.35 lb. of water from and at 212 deg. F. per lb. of coal as fired, and during the second 7.55 lb.; 1,500 lb. more water was evaporated with 1,488 lb. less of coal burned. If calculated for an equal evaporation of water, the saving in coal would be 1,700 lb. per day. The calculated saving based on the laboratory experiments was between 1,400 and 1,500 lb. per day. This saving amounts to 15 per cent of the coal burned due to covering the boiler alone, as the pipe lines were not included in the test.

NECESSITY FOR HEAT INSULATION LIKELY TO BE OVERLOOKED

The matter of insulating against heat losses has received general attention in service power plants, large factory power plants and office buildings; but unfortunately, since it invariably receives final consideration in the construction of power and heating systems, it sometimes is regarded as a luxury—added only for the sake of appearance or neglected to save investment costs. The present tendency is to practice economy, and everyone realizes the importance of conserving the natural fuel supply, and yet the few finishing touches in the way of applying a good non-heat-conducting cover to protect such losses often are overlooked. It is one chemical product that will continue to work independently of the human element of control, and for many years to come will continue to effect economies figured in the cold business way of dollars and cents.

Bluing and Browning Steel Articles

A Brief Description of Several Commercial Methods of Producing an Oxidized Finish on Polished Steel Objects, Including Analyses of Several Browning Solutions in Use in Various Establishments

By SIDNEY CORNELL

STEEL articles that have been polished and properly cleaned can be given a simple finish by immersing them in molten niter. This finish was specified for small components in rifles required by this and the allied governments during the late war. A mixture of half and half sodium and potassium nitrate is melted in a cast-iron or steel melting pot of shape and depth to suit the work. The pot should be clean prior to putting in the saltpeter, as rust from any source affects the color of the work. The niter is melted, superheated to a temperature of about 900 deg. F. (500 deg. C.) and black oxide of manganese added in the ratio of about 1 part oxide to 50 parts of niter, by volume. The manganese gives the molten salt a greenish-black tinge, and causes all suspended matter to settle to the bottom of the pot.

As bluing by this process forms an iron oxide film on the piece, consumption of the manganese oxide would be expected. Replacement at the rate of 1 lb. black oxide every three hours to a 300-lb. batch of saltpeter keeps the bath in condition. While it is doubtful what is the exact function of the manganese dioxide, this much has been observed: that if omitted from the pot the melt does not produce good work. Baths found upon analysis to be charged with iron oxide gave bad results, whereas no excess iron oxide was found in solution in any bath containing an excess of manganese oxide.

OPERATION OF NITER BATHS

In a niter bath a peacock blue or temper blue can be consistently obtained in the following manner: The articles to be blued are first cleaned, then given a thin coating of oil, then immersed in the hot niter at 600 to 650 deg. F. (315 to 345 deg. C.). The pieces may be either suspended individually on wires, or screws, nuts and other small articles may be dipped, inclosed in a wire basket. The parts are held in the niter for a few minutes, and then raised to note the depth of coloring attained, replacing in the molten salt until they reach the desired color. The time required varies with the temperature and with the size of the pieces but is never over four or five minutes.

The reaction is nothing more than obtaining a uniformly colored oxide film, as is obtained when tempering steel to color. If left in the niter too long, say ten minutes, the film produced is no longer a temper blue or a gunmetal blue, but has become a dirty gray. Preliminary cleaning in gasoline or similar solvent produces bad results, resulting in a mottled dirty surface. The oil carried on the surface of the parts takes fire immediately upon immersion in the hot niter, and if any moisture is present on the articles bad spattering of hot salt will occur.

After the right blue is obtained, the articles are quenched in cold, clean water to strike the color, then

immersed in boiling water and finally in hot oil. Hot oil dip is very necessary in treating small screws or other tiny parts, as it removes from them all moisture, which if left on the blued article will form a spot of red oxide rust, a defect which has a tendency to form at the roots of threads or any re-entrant angle.

The lower bath temperature mentioned above yields the temper blue required by the French Government for finish of rifle parts, but the United States and the British Government require a darker gunmetal blue, to obtain which a temperature up to 1,000 deg. F. (540 deg. C.) is required.

Care should be taken not to dip articles after adding manganese oxide to a niter bath until the suspended oxide has sunk, as otherwise dirty spots will appear on a blued article. Cast iron, if highly polished, will take on a gunmetal blue corresponding to that given to polished steel, but it requires about twenty minutes' immersion at 1,000 deg. F. to accomplish this result.

OIL BLACKENING

Among other coloring methods for finished work may be mentioned oil blackening, which gives a dull finish; cyanide mottling, which gives a highly colored and mottled surface, and drawing to color in a sand bath, yielding a range of color from straw to purple.

To oil blacken, the polished steel part is packed in a carburizing box, using spent carburizing compound, and properly luted to exclude air. Box and contents are heated to 1,200 deg. F. (650 deg. C.), requiring about one and one-half hours. At 1,200 deg. F. the box may be drawn, the lid opened and the parts riddled free from carburizing compound and at once quenched in oil. A black oxide-skin is formed, dull in appearance but uniform in texture. It proved to be an ideal finish for front sights for rifles.

CYANIDE MOTTLING

Cyanide mottling is obtained in a manner similar to oil blackening, except that an active carburizing compound may be used. To the spent mixture there is added approximately 5 per cent by weight of powdered potassium cyanide. Polished parts are packed in this material in a carburizing box, properly luted to exclude air, and heated to 1,200 deg. F. (650 deg. C.) for approximately four hours. Then the box is drawn, the articles are riddled free from compound and immediately quenched in oil. As air will quickly spoil the color effect, it is often advisable to quench direct from the box without riddling. If such colors as are obtained are too gaudy, the cyanide may be omitted, using pulverized charcoal in its stead.

HEAT TINTING

A beautiful finish may be obtained by simply heating polished steel articles in a sand bath. Temperatures up

to approximately 650 deg. F., (340 deg. C.) should be used, but not higher, as high temperatures tend to produce gray colored work. The sand may be on a hot plate or, better, in a cylinder capable of being slowly rotated and heated by a gas flame underneath. From five to ten minutes will produce a fine rich blue when the sand is at approximately 650 deg. F.

PARKERIZING

Parkerizing¹ and other phosphatic coatings of iron and steel yield an excellent finish. In Coslettizing, the articles, polished and cleaned, are placed in a solution of ferrous phosphate, made from iron filings, phosphoric acid and water, and the solution boiled for approximately two hours. This treatment yields a coating to steel consisting of basic iron phosphate, which is strongly adhesive. Due to the low temperature used, the physical properties of tempered steel articles are not affected, even fine springs retaining their elasticity and magnets being unaffected. The method called Parkerizing differs from Coslett's original method by adding an oxidation agent and catalyzer to the solution, usually as MnO_2 to a 0.75 per cent solution of H_3PO_4 , containing ferrous phosphate. The coating produced is then a basic ferrosophosphate, the ideal coating being one containing 3 of ferrous to 1 of ferric phosphate. After coating, the articles are gray in color, and after drying are usually coated with a paraffined oil to give them a deep black color. Considerable variation of color is possible by this treatment. When the articles are first placed in the bath a large quantity of hydrogen gas is liberated, and as soon as this ceases the process is complete. It is possible to treat a ton of parts at a cost not above \$15 to \$20.

BROWNING

There are many processes for browning steel, each of which is thought the best by its originator or user. The matter, however, may be summarized by describing one process, in spite of numerous variations, chiefly in the composition of the browning mixture. Other variations occur in manipulation and in the atmospheric conditions, artificial or natural. The longer browning processes have relatively low temperatures and humidities, while the shorter processes have relatively high temperatures and humidities. The longer processes have poor conditions, while the shorter processes have good conditions for rusting.

The operation of browning is conducted as follows:

First, applying the browning solution evenly over the surface of the article with a brush, a sponge or by dipping.

Second, keeping the article for a certain time in a

room or cabinet where good conditions for rusting are maintained.

Third, boiling the article in water to reduce ferric oxide, Fe_2O_3 , to the magnetic oxide, Fe_3O_4 .

Fourth, carding the article to remove any loose particles of oxide on the surface.

The work, coated with the solution, should be placed in a warm room or cabinet, where a temperature of about 175 deg. F. can be maintained. Dry heat is satisfactory, as it is its function merely to bring the article up to a temperature such that when it is placed in the humid rusting cabinet, dew will not form on the surface, causing spots in the color.

The rusting cabinet or room should be maintained at 175 deg. F. (80 deg. C.) and at any humidity up to the saturation point.

A third cabinet or room may also be used, although it is not absolutely necessary, conditioned the same as the first. Its object is to "set" the rust.

All of these rooms should have proper thermometers and thermostatic controls, and the rusting room a recording hygrometer. Temperature and moisture should be automatically controlled. The layout of the apparatus should permit of a proper flow of work from one process to the other.

PROCEDURES IN BROWNING

The procedures in browning are as follows:

The articles are first thoroughly cleaned, which may be accomplished by boiling for fifteen minutes in a soda solution. Any grease appearing on the surface of such a solution indicates need of soda ash addition. Then dry the parts by placing them on a draining rack. When cooled to approximately 120 deg. F. (50 deg. C.), coat with the browning solution. Dry for approximately thirty minutes, apply a second coat of the solution and dry for thirty minutes more.

The articles are then placed in the first warming room mentioned above, and brought to temperature, which may vary from 140 deg. F. up to as high as 175 deg. F. (60 to 80 deg. C.). With articles such as bayonets, thirty minutes in the warm room is sufficient. The time will naturally vary according to the size of the piece. Transfer them from the warm room to the rusting room. This must be at the same temperature as that of the warming room. Humidity up to the saturation point is desired, but danger of condensation should be avoided, as pitted and spotted work will result if the dew point is reached. Articles are rusted in approximately one hour and thirty minutes for such shapes as bayonets, others taking longer or shorter periods depending on the size and surface.

The rusted metal, now a dirty greenish red, is removed from the humid room to the third cabinet, if

¹See CHEM. & MET. ENG., vol. 21, p. 787, Dec. 24, 1919.

TABLE I. COMPOSITION OF BROWNING SOLUTIONS

Solution:		A	B	C	D	E	F	G	H	I	J	K	L	M
Ferrous chloride	$FeCl_2$										0.9			
Ferric chloride	Fe_2Cl_6	3.9	2.8	8.9	2.1	2.8	7.0			5.3	2.8	3.3	22.2	
Mercuric chloride	$HgCl_2$	1.2			0.7			3.3	4.5					10.0
Cupric chloride	$CuCl_2$						0.5	1.7						5.0
Antimony chloride	$SbCl_3$												22.2	
Bismuth chloride	$BiCl_3$							1.7						5.0
Hydrochloric acid	HCl						7.5	9.9						30.0
Ferrous sulphate	$FeSO_4$		1.5											
Cupric sulphate	$CuSO_4$	0.6			0.7	1.5				1.8		2.5		
Nitric acid	HNO_3	1.8	8.5		6.4	8.5	4.3			2.2	0.5	3.7		
Spirits of niter		6.2										4.1		
Ammonium chloride	NH_4Cl								4.5					
Alcohol	C_2H_5OH	4.0	3.2	40.1	2.4	3.2	78.2			2.6	1.4	3.7		25.0
Gallic acid	$C_7H_6O_5$												11.1

Water	H_2O	82.3	84.0	51.0	87.7	84.0		83.4	91.0	88.1	94.4	82.7	44.5	25.0
Price per gallon		\$0.90	\$0.27	\$1.45	\$0.35	\$0.30	\$3.38	\$0.86						

used, and allowed to remain for thirty minutes. Then it is placed in boiling, clean water for fifteen minutes. The articles are allowed to drain dry, and then are carded on a wire brush or fiber wheel, which operation completes the first coating.

After the first coat, three more rustings are applied in substantially the same manner. Four coatings were required to make the finish required by the British Government, after which the browned surfaces are given a coating of thin white slushing oil.

SOLUTIONS FOR BROWNING

The number of solutions in use at various places total at least a score. Many formulas prescribe copperas or logwood for use in the water in which the articles are boiled after the rusting, but since omission of both of these ingredients led to the same finishes the conclusion was drawn that they were unnecessary. The complexity of browning solutions may be judged from the analyses in Table I and it might be stated that many of the ingredients appearing in them are as unnecessary as was the logwood or copperas in the wash water. Price and performance would be the guide as to the value of browning solutions, and they are arranged in their order of merit in the table.

Creosote Evaporation From Open Tanks*

The amount of creosote lost through evaporation in open-tank treatments is in proportion to the area of the exposed surface and the volatility of the oil. At the treating temperature of 195 deg. F., the loss of creosote in lb. per sq.ft. per day may be computed from the equation,

$$\log L = 0.0165 V - 0.347$$

in which L is the loss in lb. per sq.ft. of exposed surface and V the percentage of the creosote distilling below 270 deg. C. Or the loss may be found without computation from the curve of this equation given below.

The equation and curve are applicable only when the temperature of the treating bath is in the neighborhood of 195 deg. F. At higher and lower temperatures, constants other than 0.0165 and 0.347 should be used, and these constants have not yet been determined.

BY WELLINGTON GUSTIN

Court Holds Langmuir's Patent for Incandescent Lamp Valid

Interesting facts of invention regarding the Langmuir patent 1,180,159 for the tungsten lamp are given in the recent case of General Electric Co. vs. Nitro Tungsten Lamp Co. in the U. S. Circuit Court of Appeals. The General Electric Co. is the assignee and owner of the Langmuir patent. Langmuir declares in his patent that it is not "new in the art" to use an incandescent lamp filament of tungsten, but that, though "it has been suggested in the past to introduce into a lamp bulb a neutral atmosphere at a fairly high pressure, I am not aware that any such lamps have ever been used commercially or have been technically successful." This success he sets forth in claim 4 of the patent, as follows:

"The combination of a lamp bulb, a filling therein of dry nitrogen at a pressure materially in excess of that corresponding to 50 mm. of mercury and a filament of tungsten of large effective diameter; the filament being thereby adapted for operation at a temperature higher than that which it would have if operated in a vacuum at an efficiency of one watt per candle."

Langmuir's lamp is known as the nitrogen lamp, in contradistinction to the vacuum lamp of an art about forty years old, and it was admitted that if the patent was valid the defendant was an infringer. So the trial court held defendant to account and the Court of Appeals has affirmed this.

The defendant contended that the "path of invention in respect of electric lighting has now been trodden by the feet of so many men of talent, and research even into its bypaths has been so thorough, that the first defense offered is that 'the teachings of the prior art are such as to leave no room for the exercise of patentable invention on the part of Dr. Langmuir'."

In addition to the art or knowledge of the practical man of skill in such lighting the court points out other phenomena known to the scientist. In any scheme of incandescent lighting, the energy supplied to the filament is subject to three forms of expenditure: it radiates in light waves; it escapes in heat, and is dissipated by the movement or "sweeping action" of whatever gaseous material may be in contact with the incandescent substance. The patent sets out these forms of loss as radiation, conduction and convection. The object of the vacuum was to do away with convection by dispensing with the gaseous surroundings. Raising the heat of the incandescent light giver produced more light, but the higher the heat the more rapid the deterioration of the incandescent filament. The reasons for this deterioration were obscure, says the court. The "air washing" of Edison had become an obsolete phase. But it appears that Dr. Langmuir was the first to establish, so far at least as tungsten is concerned, that to heighten heat hastened a true evaporation of the heated substance. Also introduction of an inert gas, usually nitrogen, into the lamp bulb delayed evaporation of the filament, but brought back and accentuated convection losses, which the vacuum had minimized.

When the rare and refractory metals, thorium and others, began to be hopefully regarded as possible supplanters of carbon filaments, it was suggested that if the lamp bulk be filled with a mixture of nitrogen and carburetted hydrogen the lamp would also have an excellent lighting capacity. But this was never reduced to practice. The court thought both the commercial and theoretic art had been put on a wrong road by Mr. Edison in his patent in 1883, and that before Langmuir no scientist had disclosed to the world that in the nitrogen-filled bulb the loss by convection would be diminished, and a working compromise reached between that loss and the gain in filament life, by increasing the "effective size" of the filament itself. Langmuir was also first to establish a crucial fact, that with a tungsten filament nitrogen of ordinary or commercial dryness was worse than useless.

The court found that Langmuir did not invent any nitrogen-filled bulb with any tungsten filament in it, but a special article of special proportions and a carefully stated co-ordination of parts.

Court Construes Contract of Seller Not to Engage in Similar Business

Restraint of a seller of a business from working in a similar business for a term of years was the proposition presented in the case of *Cosmos Dyeing & Printing Works vs. Calderini and others*, before the Court of Chancery of New Jersey.

It appears that under date of June 10, 1919, Delfiory Calderini and wife, doing business under the name Fiory Dyeing & Printing Co., entered into a written contract with complainant wherein the two Calderinis agreed to sell all the good will of the business of the Fiory Dyeing & Printing Co., at Haledon, Passaic County, N. J., together with all the machinery, etc., and also the land upon which the plant stood; also the processes and formulas for piece dyeing and finishing, secret or otherwise, relating to the said business. The consideration was \$185,000. The defendants further agreed not to engage in the piece dyeing and finishing business in the State of New Jersey or in the State of New York for a period of five years from August, 1919.

In this suit the Cosmos company alleged that Calderini, in violation of his agreement, did engage in the silk dyeing and finishing business with the Atlas Finishing Co., with works at Homestead, N. J., becoming its general manager. Defendant claimed that he was simply an employee at the Atlas works, and that his investment of \$10,000 in such works was made for his son so that he might learn the trade and business. Facts developed that no salary had been paid Calderini prior to the hearing on this application for an injunction to restrain his working in violation of his agreement.

Upon argument for the application for an injunction it was agreed by the defendants that all money invested in the Atlas company by Calderini in behalf of his son would be withdrawn and that the only question remaining was as to whether he could go there and labor as a paid employee. The court taking proofs on the motion to modify the restraint on Calderini held the facts insufficient for granting a preliminary injunction restraining him from working for others as an employee, despite his covenant not to engage in such business in the states of New Jersey and New York for five years. It was said the Chancery Court should go as far as possible to restrain a fraudulent act by the seller of a

business in violation of his covenant not to engage therein, but the restraint must be reasonable, and the words of the covenant carefully construed.

Moreover, the rule in New Jersey was held to be that where the complainant's right is uncertain as a matter of law, a preliminary injunction will be denied. The true intent and meaning of contract by the seller of a business not to engage therein is a question of law, particularly in view of its being one which may be in restraint of trade. The court was not willing to say on this preliminary application that the covenant prevented Calderini from working for the Atlas company. It said a preliminary injunction would not issue unless the injury sought to be prevented is irreparable.

Seller Not Responsible for Crop Failure Where Fertilizer Was Sold by Analysis

The Supreme Judicial Court of Maine has ruled that where fertilizer was sold under an agreement that it should contain certain percentages of designated ingredients, evidence that the buyer's crop failed on the land was inadmissible in an action for the price of the fertilizer, though such evidence would be admissible if the sale was accompanied by a guaranty of suitability for the proposed crop. This ruling was made in an action brought by the Bowker Fertilizer Co. against B. H. Wallingford to recover the purchase price of fertilizer sold to and used by him. The fertilizer company had judgment and this was affirmed on the appeal.

It was admitted that samples of the fertilizer were taken at the factory from the same bins from which fertilizer was taken to be shipped to Wallingford, and were analyzed by the Maine Agricultural Experiment Station. The certificate of analysis showed 4-6-10, which was in accordance with the formula printed upon the bags and barrels received by Wallingford. The company had otherwise complied with state regulations. Wallingford defended failure to pay on the ground that the fertilizer was deficient in the elements necessary to aid him in the growing of a potato crop, and further damaging the crop.

In another case it was held that proof of defendant's own experience was too uncertain, speculative or conjectural to throw any real light upon the percentage of the ingredients of the fertilizer, and that such evidence is inadmissible when sold only on a guaranteed analysis basis. (*Armour Fertilizer Works vs. Logan*, 116 Maine, 33.) But it was held that such evidence is admissible when the sale was accompanied by guaranty of suitability or results.

Now there is a rule of law that when anything is bought for a specific purpose there is an implied warranty that it is reasonably fit for that purpose. It was admitted that the fertilizer company's selling agent had knowledge that the fertilizer sold was to be used for raising potatoes; therefore, the buyer contended, the fertilizer as sold to him should have been reasonably suited for the purpose for which he bought it. But this contention was overruled by the Supreme Court.

It was said the sale was for a fertilizer of a 4-6-10 brand and nothing more. When fertilizer is sold under guaranty of analysis stated on its tag, there is no implied warranty of its suitability for the growing of a particular crop, though the seller knew that the buyer intended to use it to fertilize land for such crop. This was said to be grounded in public policy, otherwise every crop failure might be made the basis of a suit.

Manufacture of Synthetic Ammonia at Oppau, Germany*—I

Principle of the Process—Manufacture of Producer Gas and Water Gas Used in the Process—
Purification of the Gas Mixture—Catalytic Oxidation of Carbon Monoxide—
Elimination of Carbon Dioxide and Carbon Monoxide

HABER'S researches enabled him to complete the work of Le Chatelier by determining the conditions under which the maximum combination of nitrogen and hydrogen in the presence of a catalyst to form ammonia could be obtained. However, before the process could enter into commercial competition, the following problems had to be solved: The economical production of large quantities of very pure hydrogen and nitrogen; extraction of the ammonia from the gaseous mixture; conversion of the ammonia into more readily marketable products; design and construction of suitable apparatus. A staff of chemists of the Badische Anilin- und Soda-Fabrik under the direction of Dr. Mittach worked on these problems for about ten years, and their results, combined with those obtained by others not directly connected with this company, led to the adoption of the commercial process now in use.

PRINCIPLE OF THE PROCESS

The principle of the process is as follows: Water gas, $\text{CO} + \text{H}_2$, is mixed with producer gas (lean gas), $\text{CO} + x\text{N}_2$, in convenient proportions; steam is added to this mixture and the whole is passed over a catalyzer at a temperature between 400 and 500 deg. C. The carbon monoxide and steam react and give hydrogen and carbon dioxide. The carbon dioxide is dissolved in the water at a pressure of 20 to 25 kg. and the remaining gaseous mixture is freed from harmful traces of carbon dioxide and carbon monoxide by passing it through solutions of caustic soda and ammoniacal copper formate.

The resulting gaseous mixture contains about 3 volumes of hydrogen per volume of nitrogen. The

FIG. 1. SECTION OF PRODUCER-GAS BUILDING

nitrogen content is kept systematically a little below this theoretical value and additional nitrogen obtained by the distillation of liquefied air brings the mixture to the exact proportions for ammonia. This mixture is then subjected, under a pressure of 200 kg. and at a temperature of about 500 deg. C., to the action of a

second catalyzer, producing a little ammonia, which is immediately absorbed by water, and to the remaining gases which do not combine during this operation fresh amounts of gases are added and the whole is passed again through the catalyzer.

The ammonia obtained by the distillation of the solution may then be oxidized by catalysis or combined with nitric acid thus formed to give ammonium nitrate, or used for the production of ammonium chloride by the Solvay process, or for the production of ammonium sulphate by reaction with gypsum in the presence of carbon dioxide. Finally, at the Oppau plant, starting with ammonium nitrate, diverse fertilizers are manufactured, such as ammonium-potassium nitrate and a mixture of ammonium nitrate and potassium chloride sold under the name of "Mischsalz."

MANUFACTURE OF PRODUCER GAS AND WATER GAS USED IN THE PROCESS

The lean gas is furnished by a battery of gas producers, the fuel used being lignite briquets from the Cologne district.

In addition to the gas used in the production of the nitrogen-hydrogen mixture, this battery supplies gas for use under the boilers and for admixture with coal gas to form "Kraftgas," which is used in internal-combustion engines.

The water gas is furnished by a battery of coke-gas generators. The coke used is of good quality, free from sulphur, coming partly from the Ruhr district and partly from the coke ovens at the works.

The battery of lean gas producers A (Fig. 1) consists of 23 units of the Berlin Anhaltische Maschinen Aktien Gesellschaft ("B.A.M.A.G.") type and that of the water-gas generators B consists of eighteen units of the Pintsch type. Both batteries are situated in the same building, 140 x 32 m. In each battery the gas producers are located in two rows parallel to the long sides of the building and at floor level. The ashes and clinkers are emptied into underground tunnels C₁ and C₂. Storage bins D₁ and D₂, 3 m. wide and 4.5 m. high, are placed over each row of gas producers. These bins are fed by the overhead cars E₁ and E₂, carried by aerial cables, or by bucket elevators F₁ and F₂. There are four bucket elevators at each side of the building, which take the fuel from the storage tunnels running along the outside walls of the building in which the fuel brought into the plant by the cars G₁ and G₂ is stored. Under normal condition the overhead cars are used for lignite fuel and the bucket elevators for coke.

GAS PRODUCERS

The gas producers ("B.A.M.A.G.") are of sheet iron lined with refractory brick and are 2.80 m. in diameter and 3 m. high. They are divided into three groups. Each group has a common hydraulic main H and a series of washing and purifying apparatus consisting of three

*From *La Technique Moderne*, November, 1920, pp. 449-460.

washing towers 12 m. high and 1.5 m. in diameter and three rotating washers. Each of these washers is formed of two horizontal turbines 1 m. in diameter and 1.25 m. long direct connected to a 75-hp. electric motor. The two turbines are separated by a decantation vat in which the residue is collected. The gases leaving the second turbine pass through a cyclone tangential purifier with vertical axis by which the residue separates at the bottom, the gases leaving at the top through a 60-cm. diameter pipe. A bypass permits the escape of the gases to the atmosphere for a certain period when the gas producers are first started.

To facilitate supervision of the operation the gas producers are divided into groups of three units. These groups are connected to respective manipulating boards provided with six manometers indicating the pressures at the bottom

(about 310 mm.) and on top (about 130 mm.) and with means to operate hydraulically the regulating valves.

The fuel consumption is 125 kg. per hour per sq.m. of grate. The entire installation consumes 440 tons per twenty-four hours, giving 1,235,000 cu.m. of gas and 10 tons of tar—that is, about 2.8 cu.m. gas per kg. of briquets. The calorific value of the gas is 950 cal. per cu.m. and its average composition is 30 per cent CO, 67 per cent N₂ and 3 per cent CO₂. The life of the refractory lining is about two years.

WATER-GAS GENERATORS

The water-gas generators are also of sheet iron lined with refractory brick. Two units constitute a group. Each group has a common manipulating board, two scrubbers J, a double main pipe and a washing tower K. The manipulating board is provided with six manometers giving the pressures at different points and with means to operate hydraulically the regulating valves.

The gas producers are operated in cycles of four minutes, thus: Air is blown in at the bottom for one minute, the gases escaping through a chimney. Then superheated steam at 270 deg. C. and 12 kg. pressure is injected for half a minute at the bottom, then two and one-quarter minutes at the top, and finally for one-quarter minute at the bottom.

To stop the operation of the producers without extinguishing the fires it is sufficient to open portholes at the top, and the operation can be started again, even after a shutdown of twenty-four hours, by simply blowing in air for ten minutes.

The ashes and clinkers are crushed by rotating grates and dumped into underground galleries.

The fuel consumption is 100 kg. coke per hour per sq.m. of grate. The entire battery consumes 265 tons per twenty-four hours (14.75 tons per gas producer per twenty-four hours), giving 375,000 cu.m. of gas—that is, about 1.4 cu.m. gas per kg. of coke. The calorific value of the gas is 2,400 cal. per cu.m., and its average composition is 50 per cent H₂, 40 per cent CO, 4 to 6 per cent N₂, 6 to 4 per cent CO₂.

The air needed for the operation of the gas producers is carried in three conduits which are supplied respectively by one 2.5-m. diameter blower driven by a 600-hp. Brown-Boveri turbine, four 1.5-m. diameter blowers,

each driven by a 140-hp. electric motor, and one 1.5-m. diameter blower driven by a 100-hp. electric motor.

Under normal conditions the total power absorbed for supplying the air is 700 hp. Special apparatus are provided for indicating at each instant the quantity of gas in the gas holders, for the automatic recording of CO₂ content in the gases and for the calorific power of the gases (Junkers calorimeters).

PURIFICATION OF THE GAS MIXTURE

The gas mixture to be catalyzed consists of 2 parts water gas and 1 part lean gas. There are three 15,000-cu.m. gas holders, one for lean gas and two for water gas.

From the gas holders the gases pass through 1.5-m. diameter turbine type washers (four for water gas and two for lean gas), which are placed in the same building (Fig. 2). Each of these turbines is driven by a 37.5-kva. electric motor. From the turbines the water gas is led tangentially into apparatus called cyclones in which the water and the particles in suspension are separated at the bottom and the gas leaves at the top and enters the main pipes. Similarly the lean gas is sent into the respective cyclones and thence to main pipes. By a set of regulating valves the gases may be returned to the turbines for further treatment.

The circulation of the gases is controlled by four manometers, of which two are marked respectively "water-gas inlet" and "water-gas outlet" and the other two to indicate the velocities. It is probable that the quantity of water gas supplied is quite constant and that all the regulating necessary is for the needed quantity of lean gas.

The gases after passing three 10,000,000-cu.m. rotary meters (one for lean gas and two for water gas) are mixed and forced by three turbo-blowers to the catalysts for the reaction $\text{CO} + \text{H}_2\text{O}$.

CATALYTIC OXIDATION OF CARBON MONOXIDE

During the catalytic oxidation of carbon monoxide two points are of importance according to the patents of the Badische Anilin- und Soda-Fabrik—namely, the degree of porosity of the catalytic mass and the temperature regulation. The temperature has to be maintained at about 500 deg. C., because the reaction takes place only around this temperature and experience has shown that the catalytic power of the mass is destroyed at 600 to 650 deg. C.

A regulating device building is situated near the

turbine building and is electrically connected to the catalyzer building. It is from this regulating device building that the supply of the gases to the catalyzer building is controlled. The devices consist of valves, recording indicators giving at each instant the velocity of the gases through the meters, recording indicators graduated in cu.m. giving probably the volumes of the gases in the holders and Winkler burettes for gas analyses.

The different buildings through which carbon monoxide gas circulates are provided with CO indicators to give warning by sight and sound of the presence of this poisonous gas in the atmosphere of the buildings.

FIG. 2. SECTION OF TURBINE WASHERS BUILDING

FIG. 3. ARRANGEMENT OF TOWERS

At the outlet from the turbo-ventilators the gaseous mixture receives the exhaust steam from the turbines (expanded from 12 to 4 kg.) in the proportion of about 76 g. steam per cu.m. of gas mixture (0.857 kg.), and the whole enters two 17-m. towers (Fig. 3), where it

FIG. 4. SCHEMATIC ARRANGEMENT FOR THE CATALYSIS OF CARBON MONOXIDE

is heated and saturated with water vapor by jets of very hot water (about 95 deg. C.) This water comes from the washing of the catalyzed gases. The gases arriving at A in the first tower leave at B and are sent to the catalyzer. The warm water coming from the reservoirs D enters at C the reheating tower 1 and is collected in the reservoir E, whence it is brought to F and enters the tower 2 to cool the catalyzed gas which enters through G. The heated water is collected in D and the cycle can begin again.

After leaving the tower through M (Fig. 4) the gas receives an additional quantity of steam, and enters at A the heat exchanger E (1.5 m. in diameter and 7.5 m. high) and through B the first catalyzing chamber C_1 ; thence through D into the second heat exchanger E' (5 m. high), which is superposed on the first heat exchanger as shown in Fig. 5, thence through G into the

FIG. 5. SCHEMATIC ARRANGEMENT IN THE CARBON MONOXIDE CATALYZING BUILDING

second catalyzing chamber. From here the catalyzed gas passes the heat exchangers in an opposite direction following the path $FHIJ$ and enters the washing tower 2 of Fig. 3 through P. Hot gases from a Perrot furnace enter the catalyzing chambers through K_1 and K_2 and serve to bring the temperature of the catalyzers and heat exchangers to that required for good operation and leave through Z, leading to a chimney.

The catalyzing chambers are prismatic, 3 x 6 x 5.5 m., and are separated by a tight partition. In each of these sections are sheet-iron containers with the catalyzer (a mixture of iron oxide, FeO , and chromium sesqui-
